Preface

Since we published the *Atlas and Anatomy of PET/MRI, PET/CT, and SPECT/CT* in 2016, we have been using more hybrid imaging with improved equipment and software in clinical practice. Technological advances allow us to have higher quality images, and with the increasing use of new radiopharmaceuticals, we can provide more accurate evaluation of physiological processes, diagnosis, and therapeutic evaluation.

Trainees in imaging specialties and non-imaging physicians need more knowledge of detailed imaging anatomy as well as imaging analysis with pattern recognition and differential diagnosis for better patient evaluation. They should also know the different studies available and their indications, to make a more frequent and appropriate use of them in their daily practice.

In this new edition, we have included many new cases of both frequent pathologies, with their typical and atypical presentations, and infrequent pathologies. In addition, there are examples of studies with common novel radiotracers and new techniques. Each case includes relevant clinical data as well as analytical imaging description and approach, and highlights of some pathologies to provide educational information. Additional and updated bibliographic references are also included.

Atlas and Anatomy of PET/MRI

Vanessa Murad, E. Edmund Kim, Jin-Chul Paeng, Hyung-Jun Im, and Gi-Jeong Cheon

Hybrid positron emission tomography/magnetic resonance image (PET/MRI) has undergone rapid evolution during the last years, moving from a predominantly research field to clinical practice. With the advances in faster silicon photomultiplier detectors, MRI-based attenuation correction, and image reconstruction, significant improvements in equipment and image quality have been achieved. Currently, there are fully integrated PET/MRI systems that allow simultaneous and more rapid acquisition, improving not only the technical quality but also the experience for patients who need a low radiation dose [1–3]. With this technology comes the possibility of performing multiparametric MRI studies, where detailed anatomical evaluation and functional evaluation are possible, not only considering the qualitative and quantitative data of PET but also integrating multiple parameters such as perfusion (contrast-enhanced sequences), cellularity (diffusion-weighted sequence), metabolites (spectroscopic analysis), and texture analysis. Additionally, recent developments are very promising in giving the possibility of incorporating advanced data and biomarkers to integrate with

bioinformatics and allow a better understanding of the disease, as well as an efficient evaluation, prediction of response to treatment, and follow-up [4–7].

With the growing availability of PET/MRI, its main and differential applications have also been clarified. Nonspecific ^{18}F -fluorodeoxyglucose (FDG) PET/MRI continues to be the most widely used, and thus new radiotracers are expanding the field to be explored. Among the most frequent applications of ^{18}F -FDG PET/MRI, where its superiority over PET/CT has been demonstrated, are the evaluation of head and neck, colorectal, gynecological, bone and soft tissue tumors, as well as the evaluation and characterization of primary or secondary liver lesions [8–12]. It has also shown good results in non-tumor pathology such as epilepsy, inflammatory bowel disease, and cardiac sarcoidosis [4, 13].

The creation of new radiotracers that can be imaged both with PET/MRI and PET/CT, depending on the case and availability, has allowed great advances in the evaluation of other oncological and non-oncological pathologies. In the case of neuroendocrine tumors and prostate cancer, targeting somatostatin receptors with ^{68}Ga -DOTATOC, targeting PSMA with ^{68}Ga -PSMA-11 among others available tracers, and the inclusion of ^{177}Lu agents have revolutionized the diagnosis and treatment of these pathologies respectively [14, 15]. In the field of neuroimaging, the wide availability of radiotracers has made it possible to improve the evaluation of multiple targets different from glucose metabolism (FDG), such as DNA synthesis (^{18}F -fluorothymidine), protein synthesis (^{11}C -methionine, ^{18}F -fluoroethyl-L-tyrosine [FET], ^{18}F -fluoro-L-3,4-dihydroxyphenylalanine [DOPA]), and hypoxia (^{18}F -fluoromisonidazole) [16, 17]. In the field of degenerative diseases, where much remains to be explored and research is very promising, examples of emerging invaluable applications are amyloid PET and Tau PET for Alzheimer's disease, as well as ^{18}F -CIT PET for Parkinson's disease [18, 19].

In this chapter, we present multiple demonstrative examples of the different uses of PET/MR, with the most relevant anatomical references for each case.

1 Head and Neck

1.1 Case 1

A 75-year-old male patient, with worsening dizziness and weakness in both legs. Brain malignancy was suspected on

brain CT, so ^{18}F - FDG PET/MR was performed. Images revealed marked increased activity in a well-defined enhancing mass involving the corpus callosum, crossing the midline and with subependymal extension. Primary central nervous system (CNS) lymphoma was suspected, and stereotaxic biopsy confirmed a diffuse large B-cell lymphoma (Fig. 1) [20].

Fig. 1 1. Left superior frontal gyrus
2. Left precentral gyrus
3. Left postcentral gyrus
4. Peritumoral edema, right parietal lobe

5. Primary central nervous system lymphoma involving right parietal white matter
6. Primary central nervous system lymphoma involving corpus callosum

1.2 Case 2

A 72-year-old man with diagnosis of lymphoplasmacytic lymphoma (LPL)/Waldenström macroglobulinemia (WM) from marginal zone lymphoma, with central nervous system involvement. After surgery and chemotherapy, complete response was achieved, but the patient attended an early checkup with headache, so ^{18}F -FDG PET/MR was per-

formed. Images showed focal increased activity in a lobulated mass at the periventricular white matter, adjacent to the posterior horn of the left lateral ventricle with perilesional edema, which showed predominantly low signal on T2WI and heterogeneous contrast enhancement, which are frequent findings of lymphoma involvement. With these findings, a relapse was confirmed, and treatment was initiated again (Fig. 2) [21].

Fig. 2 1. Metabolically active lymphoma adjacent to the posterior horn of the left lateral ventricle
 2. Normal FDG uptake in gray matter at the frontal cortex

 14. Superior sagittal sinus

1.3 Case 3

A 5-year-old patient with gradual loss of vision in the right eye. Clinical examination and contrast-enhanced MRI were performed and confirmed the diagnosis of retinoblastoma.

^{18}F -FDG PET/MR was performed during initial workup and staging. Minimal uptake was found in the primary tumor and the presence of metabolically active metastases was ruled out (Fig. 3) [22].

Fig. 3 1. Right eye retinoblastoma with minimal diffuse FDG uptake

 14. Basilar artery
 15. Fourth ventricle

1.4 Case 4

A 49-year-old woman with a headache and decreased mobility of the right eye. ¹⁸F-FDG PET/MR was performed, and images showed a metabolically active mass with heterogeneous enhancement in the olfactory recess involving the

cribriform plate and ethmoid air cells. The lesion produced lateral displacement of the right medial rectus muscle, compression of the optic chiasm, and obstruction of the sphenoid sinuses. Subsequent biopsy confirmed the diagnosis of an olfactory neuroblastoma, also known as esthesioneuroblastoma (Fig. 4) [23].

1.5 Case 5

A 48-year-old male patient with progressive proptosis, impaired visual acuity, and headaches. ^{18}F -FDG PET/MR was performed, finding diffuse metabolically active infil-

tration of the soft tissues in both orbits and eyelids, with encasement and displacement of the optic nerves and muscles, without infiltration. Biopsy revealed the diagnosis of an extra nodal marginal zone B-cell lymphoma (EMZBC) (Fig. 5) [22].

24. Midbrain, sustancia nigra

1.6 Case 6

A 55-year-old male patient with sore throat and a soft tissue mass in the right nasopharyngeal wall on physical examination. Biopsy revealed nasopharyngeal squamous cell carcinoma, so ^{18}F -FDG PET/MR was performed for staging.

Images showed increased metabolic activity in the right nasopharyngeal area at a soft tissue mass, consistent with the primary tumor. Hypermetabolic, enlarged, metastatic lymph node (LN) was also found in the right neck, level II (Figs. 6 and 7) [24].

 7. Right external maxillary vein

8. Right parotid gland
 9. Metabolically active LN metastasis, right neck level II
 10. Oropharynx
 11. Spinal cord

1.7 Case 7

A 55-year-old female patient with a growing ulcerated mass in the right sublingual area. Biopsy was performed confirming an adenoid cystic carcinoma with cribriform pattern, so

^{18}F -FDG PET/MR was performed for staging. Images showed a focal hypermetabolic lesion in the right sublingual space, displacing the tongue's intrinsic muscles, without infiltrating them. Ipsilateral, level II, hypermetabolic lymph node metastasis was also found (Fig. 8) [10].

Fig. 8 1. Metabolically active tumor in the right sublingual space
 2. Metastatic LN, right neck level II
 3. Genioglossus muscle
 4. Epiglottis
 5. Larynx
 6. Cervical vertebral body

 9. Left submandibular gland
 10. Right common carotid artery
 11. Left sublingual space
 12. Mandible, body

1.8 Case 8

A 55-year-old male patient with a history of persistent dysphagia and cough. Direct endoscopic examination was performed finding a laryngeal mass, consistent with an epiglottic

squamous cell carcinoma. ^{18}F -FDG PET/MR was performed for staging, finding a prominent hypermetabolic mass in the superior aspect of the epiglottis, projecting towards the upper airway and decreasing its caliber. No hypermetabolic lymph nodes or distant metastases were observed (Fig. 9) [10].

Fig. 9 1. Metabolically active epiglottic tumor

7. Nasopharynx
8. Uvula
9. Oropharynx
10. Larynx

1.9 Case 9

A 21-year-old man with a non-painful, progressively growing right parotid mass. Ultrasound-guided biopsy revealed a secretory carcinoma, so ¹⁸F-FDG PET/MR was performed

for staging. Images showed a hypermetabolic irregular mass involving both the superficial and deep lobes of the right parotid gland, without associated metastatic lymph nodes (Fig. 10) [25].

Fig. 10 1. Metabolically active right parotid tumor, involving both superficial and deep lobes

 4. Left parapharyngeal space

5. Left carotid space
 6. Left paraspinal space
 7. Left buccal space
 8. Oropharynx
 9. Longus capitis muscles

1.10 Case 10

A 57-year-old man with a painful, rapidly growing left cervical mass. Ultrasound was performed finding an enlarged, necrotic lymph node, which biopsy revealed a metastatic carcinoma. ^{18}F -FDG PET/MR was performed suspecting pri-

mary head and neck malignancy, and images showed a hypermetabolic mass in the hypopharynx, predominantly left side, with multiple metastatic lymph nodes in the left neck. The diagnosis of primary squamous cell carcinoma in this location was confirmed (Fig. 11) [10].

Fig. 11 1. Metabolically active hypopharyngeal tumor
 2. Hypermetabolic metastatic neck lymph nodes: left, level III
 3. Hypermetabolic metastatic neck lymph node: left, level II
 4. Hypermetabolic metastatic neck lymph nodes: left, level IV
 5. Right carotid artery
 6. Retropharyngeal space
 7. Right vertebral artery

 10. Left carotid artery
 11. Left jugular vein
 12. Trachea
 13. Left thyroid lobe
 14. Left common carotid artery
 15. Left second rib
 16. Vocal cords

1.11 Case 11

A 22-year-old man with headache, occasional fever, and weakness in both arms. Laboratory tests did not show definite abnormalities, so ^{18}F -FDG PET/MR and MRI were performed to rule out unknown origin infection vs occult

malignancy. Images showed diffusely increased activity along the spinal cord with corresponding ill-defined high signal intensity lesions in T2WI. With these findings and other neurological tests, the diagnosis of acute disseminated encephalomyelitis (ADEM) was confirmed (Fig. 12) [26].

1.12 Case 12

A 67-year-old male patient with a history of left maxillary sinus squamous cell carcinoma, treated 9 years ago with radiotherapy and surgery (resection with flap reconstruction). He attended his annual checkup completely asymptomatic

and among other studies ^{18}F -FDG PET/MR was performed. Images showed focal increased activity in the lateral wall of the left nostril on the medial aspect of the surgical flap, which also presented heterogeneous contrast enhancement, which was not evident in the previous study. This finding was confirmed as a local recurrence (Fig. 13) [10].

2 Chest

2.1 Case 1

A 62-year-old male patient with a solitary pulmonary nodule and history of heavy smoking. ^{18}F -FDG PET/MR was per-

formed during staging. Images showed moderately increased activity in a small solid nodule at the left lower lobe, which was later resected and confirmed as an adenocarcinoma. No metabolically active metastases were detected (Figs. 14, 15, 16, 17, 18, and 19) [27, 28].

2.2 Case 2

Chest X-ray was performed on a 43-year-old woman due to a history of tuberculosis. A mediastinal mass was found, so evaluation with ¹⁸F-FDG PET/MR was indicated. Images

showed mild focal increased activity at an oval, well-defined mass in the anterior and superior mediastinum as the only finding. Posterior biopsy confirmed a low-grade thymoma, type A (Fig. 20) [29].

Fig. 20 1. Anterior mediastinal mass with mild, diffuse FDG uptake: low-grade thymoma

 8. Right pulmonary artery
 9. Sternum
 10. Left pulmonary artery
 11. Descending aorta
 12. Superior vena cava

2.3 Case 3

A 39-year-old woman with family history of breast cancer (two sisters), who attended with a palpable mass in the right breast. Initial studies confirmed an invasive ductal carcinoma, so ^{18}F -FDG PET/MR was performed for staging.

Images showed a metabolically active mass in the right breast with metastatic axillary lymph nodes in levels I and II. Intense FDG uptake was found in the left ventricular wall, probably related to poor fasting (Figs. 21 and 22).

Figs. 21 and 22 1. Metabolically active tumor in the right breast
 2. Right ventricle
 3. Left ventricle (diffuse myocardial uptake)

 15. Aortic arch
 16. Left axillary fossa
 17. Sternum
 18. Trachea

3 Abdomen and Pelvis

3.1 Case 1

A 60-year-old male patient with weight loss of 10 kg over 7 months. Endoscopy and biopsy confirmed the diagnosis of a gastric adenocarcinoma, so ^{18}F -FDG PET/MR was done

for initial staging. Images showed a hypermetabolic lesion along the lesser curvature of the stomach, corresponding to the primary tumor. Another focal lesion with increased activity was found in the liver S5, which was confirmed as a liver metastasis [30]. As an incidental finding, a cystic lesion was observed in the left perineal soft tissues, which corresponded to a dermoid cyst (Figs. 23, 24, and 25).

3. Right proximal femur
4. Penis

3.2 Case 2

A 69-year-old female patient with a history of right nephrectomy 10 years ago due to a renal liposarcoma, who presented with abdominal discomfort. Endoscopy was done and revealed a signet-ring cell gastric cancer, so ^{18}F -FDG PET/MR was done for initial staging. Focal increased activity was

observed in the gastric antrum corresponding to the primary tumor, as well as in several enlarged lymph nodes (LNs) in the lesser curvature area, metastatic. Additionally, mild, diffuse, increased activity was found in fat-attenuating lesions at the retrocrural area and peritoneum, which were consistent with recurred liposarcoma (Figs. 26 and 27) [30, 31].

 14. Abdominal aorta

3.3 Case 3

A 74-year-old male patient with persistent abdominal pain during the last 3 months. Ultrasound was performed finding a suspicious mass in the gallbladder, so he was referred for ^{18}F -

FDG PET/MR evaluation. Images showed a marked hypermetabolic mass in the gallbladder fundus with intermediate, heterogeneous signal intensity in T2WI, consistent with a primary adenocarcinoma. Hypermetabolic liver invasion was excluded, as well as distant metastases (Fig. 28) [32].

 6. Pancreatic tail

7. Left kidney, superior pole
 8. Spleen, inferior pole
 9. Gallbladder stones
 10. Cystic duct
 11. Portal vein
 12. Abdominal aorta

3.4 Case 4

A 42-year-old patient, hepatitis B virus carrier, underwent abdominal ultrasonography for a routine health check. A liver mass was found, so ¹⁸F-FDG PET/MR was indicated for further evaluation. Images showed moderate focal increased

activity in the liver S7 at a lobulated mass with arterial enhancement and delayed washout, consistent with a hepatocarcinoma. The patient underwent right liver posterior sectionectomy and the final diagnosis was combined hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCA), which explains the high FDG uptake of the lesion (Fig. 29) [33].

Fig. 29 1. Metabolically active liver tumor with heterogeneous arterial enhancement and delayed washout
 2. Right hepatic vein
 3. Middle hepatic vein

4. Left hepatic vein
 5. Inferior vena cava
 6. Abdominal aorta
 7. Spleen

3.5 Case 5

A 58-year old patient with a history of a rare liver schwannoma, who presented with abdominal mass. ^{18}F -FDG PET/MR was done to search for malignant transformation. Images

showed mild focal increased activity at the solid component of a complex irregular mass in the liver dome, which also showed heterogeneous signal intensity and delayed enhancement. Excisional biopsy was done, and a schwannoma with malignant transformation was confirmed (Figs. 30 and 31) [34].

2. Physiologic myocardial uptake, left ventricle
3. Descending aorta

Fig. 31 1. Main portal vein
2. Metabolically active liver schwannoma with delayed enhancement and central necrosis

3. Abdominal aorta
4. Stomach

3.6 Case 6

A 72-year-old woman with recurrent abdominal pain, weight loss, and fever. Initial studies confirmed the diagnosis of a pancreatic tail adenocarcinoma and due to the suspicion of liver metastases, ^{18}F -FDG PET/MR was indicated. Images

showed focal increased activity in a hypovascular pancreatic tail mass consistent with the primary tumor; due to the location of the lesion, no dilation of the main pancreatic duct was observed. Additionally, multiple focal hypermetabolic liver lesions were identified in the right hepatic lobe, corresponding to metastasis (Fig. 32) [32].

10. Superior mesenteric artery
11. Abdominal aorta
12. Splenic artery
13. Left adrenal gland

3.7 Case 7

A 69-year-old woman with persistent abdominal pain and distention. Abdominal ultrasound showed biliary dilatation and a suspicious pancreatic mass. ¹⁸F-FDG PET/MR was

done finding a hypermetabolic mass in the pancreatic head with dilatation of the main pancreatic duct and atrophy of the distal pancreatic parenchyma, typical findings of an adenocarcinoma at this location. No metabolically active metastases were detected (Fig. 33) [32].

 9. Inferior vena cava
 10. Right adrenal gland
 11. Common bile duct, distal portion
 12. Main pancreatic duct dilatation
 13. Abdominal aorta
 14. Spleen

3.8 Case 8

An 80-year-old woman with bloating, heaviness, and abdominal distention. Endoscopy was done finding a prominent mass in the stomach, so ^{18}F -FDG PET/MR was performed. Images showed slight and diffuse increased activity in a

prominent rounded and very well-defined mass at the stomach, with heterogeneous contrast enhancement due to the presence of necrosis. Surgical resection of the lesion was done, and the final diagnosis was a low-grade gastrointestinal stromal tumor (GIST), as suspected (Fig. 34) [35].

Fig. 34 1. Metabolically active gastric GIST

9. Right hepatic lobe, segment 6 (VI)
10. Right kidney, inferior pole
11. Right adrenal gland
12. Abdominal aorta
13. Left adrenal gland
14. Left perirenal space

3.9 Case 9

A 59-year-old man with a 3-month history of gradually increasing rectal bleeding. Colonoscopy was performed finding a circumferential mass in the sigmoid colon, consistent with an adenocarcinoma. During initial staging, liver metas-

tases were suspected, so ^{18}F -FDG PET/MR was performed. Images show intense FDG uptake in the sigmoid colon at the primary tumor, without hypermetabolic pelvic or retroperitoneal lymph nodes. However, multiple metabolically active liver metastases were identified in both lobes (Fig. 35) [36].

Fig. 35 1. Metabolically active sigmoid colon adenocarcinoma

 11. Left internal iliac vessels

3.10 Case 10

A 74-year-old man with prostate cancer, Gleason 8 (4 + 4), diagnosed with multiparametric MRI and transrectal biopsy. ^{18}F -Choline PET/CT was performed for staging and images showed focal increased activity in the primary tumor at the left peripheral zone of the prostate gland with exophytic

extension to the recto-prostatic angle and probable involvement of the neurovascular bundle (see MRI correlation). Also, two different metastatic bone lesions were observed, one slightly hypermetabolic, ill-defined intramedullary lesion in the right ischial tuberosity, and other cortical sclerotic lesion in the left ischial tuberosity without FDG uptake (Fig. 36) [15].

Fig. 36 1. Focal increased activity at primary prostate cancer in the left peripheral zone

 33. Anal canal
 34. Right gluteus maximus muscle

3.11 Case 11

A 41-year-old woman referred for ¹⁸F-FDG PET/MR due to abnormal findings on her annual general checkup. At colonoscopy, a lobulated subepithelial mass was found on the

anterior aspect of the rectum; there was no definite abnormal increased activity in the lesion, which was later confirmed as a leiomyoma. Also, a complex right adnexal cystic mass without abnormal increased FDG uptake was observed; the final diagnosis was a hemorrhagic cyst (Figs. 37 and 38) [36].

3.12 Case 12

A 59-year-old female patient with an abnormal Pap smear test. Cervical punch biopsy revealed a squamous cell carcinoma, so ^{18}F -FDG PET/MR was done for initial staging.

Images showed a hypermetabolic mass in the uterine cervix involving the posterior upper vaginal wall, but not the parametrium. No abnormal hypermetabolic lesions suggesting metastasis were found (Figs. 39 and 40) [37, 38].

3.13 Case 13

A 41-year-old female patient with vaginal bleeding. Cervical biopsy revealed a squamous cell carcinoma, so ^{18}F -FDG PET/MR was done for staging. Images showed a hypermeta-

bolic uterine cervical mass involving the parametrium and the lower third of the vagina. Hypermetabolic and enlarged metastatic LNs were also found in both the external iliac and left internal and perirectal areas (Figs. 41, 42, 43, and 44) [37, 38].

4 Musculoskeletal System

4.1 Case 1

A 42-year-old female patient with a palpable mass in the right lower leg. ^{18}F -FDG PET/MR was performed for further evaluation, finding a multilobulated soft tissue mass with moderately increased activity at the posterior compartment

of the right lower leg. Enlarged LNs with mildly increased metabolism were also observed in the right external iliac, inguinal, and popliteal regions. Posterior biopsy confirmed synovial sarcoma in the primary mass, and reactive inflammatory LNs in other locations, which is an expected finding since sarcomas very rarely metastasize to LNs (Figs. 45, 46, 47, 48, and 49) [39, 40].

4.2 Case 2

A 39-year-old male patient with a palpable mass in the right thigh. ^{18}F -FDG PET/MR was done for initial evaluation and

staging. Images showed mild increased activity at a well-margined enhancing mass in the right inner thigh. Myxoid liposarcoma was revealed by needle biopsy (Fig. 50) [39].

7. Femoral vessel
8. Sartorius muscle
9. Gracilis muscle
10. Biceps femoris muscle

4.3 Case 3

A 16-year-old female patient with chronic pelvic pain. X-ray and CT scan revealed an aggressive bone lesion in the left pelvic bone, and needle biopsy confirmed the diagnosis of osteosarcoma, so ^{18}F -FDG PET/MR was performed for staging. Images showed increased activity at a destructive bony

lesion in the left pelvic bone involving the ilium, sacrum, and acetabulum, and encasing the left internal iliac vessels and sacral plexus. Inside the mass, an area with signal void on T2WI and marked contrast enhancement was identified, suggestive of intratumoral aneurysm. Multiple mild hypermetabolic metastatic lung nodules were also found (Figs. 51 and 52) [41, 42].

Atlas and Anatomy of PET/CT

Vanessa Murad, E. Edmund Kim, Jin-Chul Paeng,
Camilo Barragan, and Gi-Jeong Cheon

PET/CT is a combined system of positron emission tomography (PET) and computed tomography (CT) scanners. PET can detect abnormal metabolic activity in organs or lesions even before they show morphological changes and CT enables precise localization, so co-registration of functional and anatomic information is achieved in the same study, obtained on the same scanner [1]. This technology, available now for at least 10 years, has allowed great advances especially in the field of oncology, and every day it opens more fields to explore in this and other multiple pathologies [2]. Nowadays there is also the possibility of carrying out total body PET studies, which encompasses the entire body within the field of view of the scanner, allowing imaging of all the tissues and organs simultaneously. The increase in geometric coverage of total body PET and multiple adjusted parameters make the whole-body image a very sensitive study with major implications for medical imaging.

PET/CT is currently widely available in the world and many guidelines already recommend it as part of the diagnosis, staging, follow-up, or re-evaluation of various pathologies. As for PET/MR, nonspecific ^{18}F -FDG is the most widely used available radiotracer for PET/CT studies, and thus many other

new tracers are available or under investigation, to offer better possibilities to patients and not only in the field of oncology [2, 3]. Indications for FDG PET/CT are continuously evolving according to the advances that current research allows; however, in oncology it can be useful in various stages of the disease depending on the pathology: initial diagnosis, staging, therapeutic approach, evaluation of response to treatment and recurrence. A great example, and perhaps one of the most frequently used with multiple indications is lymphoma [3, 4]. Other frequent scenarios in which it has a diagnostic utility are the evaluation of a solitary pulmonary nodule, multiple myeloma, and search for a primary tumor of unknown origin [5–7]. Its usefulness in staging due to the ability to evaluate the whole body, detect lymph node or distant metastasis, and offer some prognostic information can be extended to almost all cancer pathology, but it has been evaluated with better results in melanoma, head and neck, lung, colorectal, gynecological and esophageal cancers among others, as well as in bone and soft tissue sarcomas [3, 8–11]. Likewise, in some cases such as lung, esophageal, and colorectal cancers, it has shown great utility in radiotherapy planning with excellent results [12, 13]. Response assessment utility depends on the characteristics of the primary tumor and stage, but in lung, esophageal, and colorectal cancers, the results have been promising [10, 13, 14]. Finally, in the evaluation of recurrence, its diagnostic accuracy may also be subject to the characteristics of the primary tumor, but since a large part of the metastases are more aggressive and metabolically active, it represents a good tool for almost all tumors, especially for head and neck, lung, gynecological, and bone and soft tissue tumors. It is important to bear in mind that although it is not indicated for the diagnosis or staging of a series of non-FDG avid tumors (stomach, pancreas, hepatoma, genitourinary tract, ovary, among others), when there is a suspicion of relapse it may play an important role [3, 15, 16].

As in PET/MRI, the availability of multiple novel radiotracers has allowed great advances, especially in neuroendocrine tumors, prostate cancer, and neuro-oncology and degenerative diseases, having the same tracers previously described available for PET/CT studies [17].

In this chapter, we present multiple demonstrative examples of the different uses of FDG and non-FDG PET/CT, with the most relevant anatomical references for each case.

1 ¹⁸F-FDG PET/CT

1.1 Head and Neck

1.1.1 Case 1

A 56-year-old female patient with frontal headaches during the last 3 months. Brain ¹⁸F-FDG PET/CT was performed for

malignancy work-up. Images showed mild and irregular increased activity in the cingulate cortex and corpus callosum, at a lobulated and calcified extra axial mass, and later proved to be a meningioma (WHO grade I). The increased activity in this case may represent an artifact due to the dense and irregular calcification, rather than a definite uptake by the mass (Figs. 1 and 2).

Fig. 1 1. Left superior frontal gyrus
 2. Left middle frontal gyrus
 3. Calcified meningioma in the corpus callosum
 4. Perilesional edema in the posterior left periventricular area
 5. Falx cerebri

 5. Right lateral ventricle, anterior horn
 6. Right putamen

7. Right cistern of lateral cerebral fossa (insular cistern)
 8. Right thalamus
 9. Right lateral ventricle, posterior horn
 10. Straight sinus
 11. Superior sagittal sinus

1.1.2 Case 2

A 65-year-old woman with a history of lung squamous cell carcinoma undergoing chemotherapy, who attended her routine follow-up completely asymptomatic. ^{18}F -FDG PET/CT was performed finding a newly developed focal hypometabolic

lesion in the left parietal cortex with peripheral mild, diffuse hypometabolism, which was confirmed to be a metastatic lesion with surrounding edema on contrast MRI (Figs. 3 and 4) [18].

Figs. 3 and 4 1. Right parietalcortex, precentral gyrus
 2. Hypometabolic metastasis in left parietal cortex
 3. Right frontal cortex, superior frontal gyrus
 4. Diffuse hypometabolism in the left parietal cortex and white matter representing perilesional edema

 19. Frontal sinuses
 20. Left sphenoid bone
 21. Left mastoid air cells

1.1.3 Case 3

A 17-year-old male patient with persistent headache and obstructive hydrocephalus on brain CT. ¹⁸F-FDG PET/CT was performed finding two lesions, one located in the suprasellar region and the other in the pineal region. Both lesions showed very low FDG uptake and heterogeneous density

with cystic components and calcifications. Biopsy revealed the diagnosis of bifocal germinoma, which can be found in 2–18% of cases. It remains unclear if this represents synchronous tumors or metastatic disease, but it is known that these patients have a worse prognosis (Fig. 5) [19].

- 18. Left eye vitreous chamber
- 19. Left optic nerve
- 20. Choroid plexus at the right lateral ventricle

1.1.4 Case 4

A 64-year-old man with occasional headache. Initial brain CT revealed an expansive heterogeneous lesion in the clivus, so ^{18}F -FDG PET/CT was performed to determine its nature. Images showed minimal diffusely increased activity in an expansive, well-defined, lytic lesion in the superior and cen-

tral aspect of the clivus. These findings favored the diagnosis of a chordoma, which differs from chondrosarcoma because the latter generally presents greater FDG uptake and a chondroid matrix with typical calcifications in rings and arcs (Fig. 6) [20].

23. Foramen magnum
24. Clivus
25. Sella turcica/pituitary gland

1.1.5 Case 5

A 65-year-old man with progressive hoarseness. In otolaryngology consultation, physical examination and laryngoscopy revealed a tiny lesion in the right side of the glottis. Biopsy confirmed a squamous cell carcinoma, so ^{18}F -FDG PET/CT

scan was requested for staging. Images showed focal increased uptake in the right side of the glottis, at the site of the primary tumor, which represents a metabolic change without an evident anatomical abnormality. No hypermetabolic lymph nodes or distant metastases were found [9] (Figs. 7 and 8).

Figs. 7 and 8

35. Trachea

1.1.6 Case 6

A 45-year-old woman with progressive enlargement of the thyroid gland and occasional pain. Ultrasound and ultrasound-guided biopsy confirmed the diagnosis of diffuse,

large B-cell lymphoma, so ¹⁸F-FDG PET/CT was performed for staging. Images showed marked increased activity in the diffusely enlarged thyroid gland. No hypermetabolic lymph nodes or distant metastasis were noted (Fig. 9) [21].

 15. Left interpectoral area
 16. Posterior cervical fat
 17. Left pulmonary apex

1.1.7 Case 7

An 85-year-old man with odynophagia. Physical examination revealed enlargement and ulceration of the right palatine tonsil and biopsy confirmed the diagnosis of a squamous cell carcinoma, so FDG was performed for staging. Images

showed focal increased activity in the right palatine tonsil at the primary tumor, as well as two hypermetabolic metastatic lymph nodes in the right upper neck, level II. Note the obliteration of the right parapharyngeal space, which is one of the indirect signs of lesions at this location (Fig. 10) [9].

Fig. 10 1. Metabolically active primary tumor in the right tonsil

 16. Left submandibular gland
 17. Left vertebral foramen
 18. Spinal canal

1.2 Chest

1.2.1 Case 1

A 25-year-old man with rapid weight loss. Initial studies showed high alpha-fetoprotein (AFP) and a mediastinal mass in the chest X-ray, so ^{18}F -FDG PET/CT was performed on

suspicion of a germ cell tumor. Images showed a well-defined, cystic-necrotic anterior mediastinal mass, with a peripheral hypermetabolic solid component, which suggested a more aggressive behavior favoring a non-seminomatous tumor. Posterior biopsy confirmed the diagnosis of a yolk sac tumor (Fig. 11).

Fig. 11 1. Primary tumor with large cystic-necrotic component and hypermetabolic solid peripheral component

7. Left scapula

8. Superior vena cava

9. Ascending aorta

10. Main pulmonary artery

11. Left main bronchus

12. Right atrium, superior aspect

13. Esophagus

1.2.2 Case 2

A 43-year-old woman with occasional dyspnea and chest tightness. Chest X-ray and CT were performed, finding a mediastinal mass and considering lymphoma or thymoma as differential diagnoses, so ^{18}F -FDG PET/CT was performed.

Images showed an irregular, well-defined anterior mediastinal mass, with an adequate cleavage plane with the vascular structures, with mild homogeneous FDG uptake. With these findings, the diagnosis of low-grade thymoma was suggested and biopsy confirmed a type AB thymoma (Fig. 12) [22].

Fig. 12 1. Anterior mediastinal mass with mild homogeneous FDG uptake, consistent with thymoma type AB

11. Aortic root
12. Right ventricle
13. Right atrium
14. Left pericardial recess

1.2.3 Case 3

A 50-year-old man with progressive dyspnea and chest pain. Chest X-ray and CT showed an anterior mediastinal mass, so ^{18}F -FDG PET/CT was performed. Images showed a large, irregular, but not infiltrative, mild, metabolically active ante-

rior mediastinal mass with dystrophic calcifications. Extensive pleural invasion with the same mild, diffuse uptake as the primary tumor was observed. The findings suggested a low-grade thymoma and later biopsy confirmed a thymoma type B1 (Fig. 13) [22].

Fig. 13 1. Slight hypermetabolic anterior mediastinal mass corresponding to thymoma type B1
 2. Thymoma type B1, left superior aspect with dystrophic calcifications

 10. Left main bronchus
 11. Sternum
 12. Descending aorta
 13. Right internal mammary vessels
 14. Pericardial fat

1.2.4 Case 4

A 58-year-old patient with atypical and occasional chest pain who underwent an echocardiogram, finding a poorly defined mediastinal lesion. Contrast CT and ^{18}F -FDG PET/CT revealed a poorly defined infiltrative mediastinal lesion with

high and homogeneous FDG uptake, as well as a right inferior pleural seeding. The findings were suspicious of a high-grade thymoma, and postsurgical pathology of the pleural lesion confirmed the diagnosis of a thymoma type B3 (Fig. 14) [22].

Fig. 14 1. Increased activity in the infiltrating mass, consistent with thymoma type B3
 2. Metabolically active right lower lobe pleural seeding

 11. Left upper lobe
 12. Left ventricle
 13. Lower esophagus
 14. Right ventricle
 15. Right atrium
 16. Left lower lobe

1.2.5 Case 5

A 58-year-old female patient with a history of diffuse, large B-cell lymphoma with lymph node involvement, treated with chemotherapy achieving complete metabolic response. In the last ^{18}F -FDG PET/CT checkup, multiple new hypermetabolic mediastinal lymph nodes were noted, with a distribution in bilateral hilar, subcarinal, and right paratracheal areas

(lambda sign). Also, diffusely increased activity was detected in the soft tissues of the lower lumbar region and left gluteal region. Given the suspicion of lymphoma recurrence, biopsy of both the lymph nodes and the soft tissue lesions was performed, where chronic granulomatous changes consistent with sarcoidosis were reported (Fig. 15).

Fig. 15 1. Metabolically active mediastinal lymph nodes, lambda sign
 2. Ascending aorta
 3. Right hilar lymph nodes, level 10R
 4. Right main bronchus
 5. Subcarinal lymph nodes, level 7

 15. Left iliac wing
 16. Left sacroiliac joint
 17. Increased activity at left gluteal soft tissue involvement
 18. Right gluteus maximus muscle
 19. Sacrum
 20. Left acetabular roof
 21. Metabolically active intergluteal lymph node

1.2.6 Case 6

A 51-year-old man with dyspnea and chest pain, with normal chest X-ray. Suspecting pulmonary embolism (PE), chest CT angiography was requested, finding an extensive filling defect in the pulmonary trunk, the entire right pulmonary artery and the branch for the superior lobe, as well as in the proximal left pulmonary artery. However, the filling defect

was irregular and showed enhancement, indicating that it was more likely a soft tissue lesion or a tumor thrombus, so ^{18}F -FDG PET/CT was performed. Images showed marked increased activity in the irregular intravascular lesion without other findings. A primary angiosarcoma of the pulmonary artery was suggested as the diagnosis, which was later confirmed with biopsy (Fig. 16) [23].

Fig. 16 1. Metabolically active tumor in the pulmonary artery
 2. Angiosarcoma involvement at the main pulmonary artery
 3. Angiosarcoma involvement at the right pulmonary artery
 4. Angiosarcoma involvement at the right upper lobe artery

 15. Left main bronchus
 16. Left upper lobe pulmonary artery
 17. Thoracic vertebra left transverse process
 18. Esophagus
 19. Right costovertebral joint

1.2.7 Case 7

A 28-year-old woman with occasional chest pain. Chest X-ray was performed finding a mediastinal mass, so ^{18}F -FDG PET/CT was ordered for further evaluation. Initial images (superior) showed intense FDG uptake in a bulky anterior mediastinal mass, as well as metabolically active enlarged lymph nodes at the lower neck and right cardio-

phrenic and left retroperitoneal areas. The diagnosis of primary mediastinal B-cell lymphoma was confirmed and first-line chemotherapy was started. Two cycles later, in the follow-up ^{18}F -FDG PET/CT, complete metabolic resolution of the previously visualized lesions was observed. This unique and rare subtype of non-Hodgkin lymphoma occurs in only 2–3% of cases (Fig. 17) [24].

Fig. 17 1. Metabolically active bulky anterior mediastinal mass
 2. Hypermetabolic enlarged lymph nodes in the bilateral lower neck
 3. Focal increased activity in right cardiophrenic lymph node
 4. Focal increased activity in left retroperitoneal lymph node
 5. Focal increased activity in right hilar lymph node

 20. Left rib, lateral arc
 21. Carina
 22. Superior vena cava
 23. Esophagus

1.2.8 Case 8

A 54-year-old woman with diagnosis of infiltrating ductal carcinoma of the left breast and suspected axillary lymph node metastases. As part of staging, ^{18}F -FDG PET/CT was performed. Images showed diffuse, increased activity in the left breast, predominantly toward the lower outer quadrant, where the primary lesion was confirmed. Furthermore, mul-

iple metabolically active lymph node metastases were observed at all left axillary levels, supraclavicular region, and mediastinum. In the normal right breast parenchyma, diffuse FDG uptake is perceived, which represents normal physiologic activity frequently seen in premenopausal women (Figs. 18 and 19) [25].

Fig. 18 1. Hypermetabolic diffuse infiltrative left breast cancer
 2. Multiple hypermetabolic lymph node metastasis
 3. Normal right breast tissue with mild, diffuse FDG uptake
 4. Right internal mammary chain, normal

 12. Right thyroid lobe with mild, diffuse uptake
 13. Hypermetabolic left supraclavicular lymph nodes
 14. Left deltoid muscle
 15. Left trapezius muscle

1.2.9 Case 9

A 48-year-old woman with progressive pain, redness, and hardening of the left breast, associated with bloody nipple discharge. Ultrasound and biopsy were performed confirming the diagnosis of an inflammatory carcinoma and ^{18}F -FDG PET/CT was requested for staging. Images showed a meta-

bolically active multifocal left breast cancer with increased activity at marked skin thickening. Multiple hypermetabolic metastatic lymph nodes were also observed, predominantly in the axillary level I, as well as same-side interpectoral area and internal mammary chain (Fig. 20) [25].

 16. Right lung apex
 17. Left first rib, anterior arc
 18. Interpectoral lymph node (Rotter) metastasis
 19. Left major pectoralis muscle
 20. Left second rib, posterior arc

1.2.10 Case 10

An 80-year-old male patient with history of scalp angiosarcoma, treated with surgery and chemotherapy. Follow-up ^{18}F -FDG PET/CT was performed 8 months after surgery and showed multiple new lesions, including a small left upper lobe pneumothorax chamber, increased activity at a right

middle lobe ground glass opacity, and multiple randomly distributed, thin-walled cystic lesions, some with peripheral FDG uptake. Hypermetabolic lymph nodes were also noted in the subcarinal and bilateral hilar areas. Ultrasound-guided endobronchial biopsy revealed the suspected diagnosis: angiosarcoma metastasis (Fig. 21) [26].

Fig. 21 1. Metabolically active right hilar lymph nodes
 2. Diffusely increased activity in ground-glass opacities at the right middle lobe
 3. Left renal pelvis
 4. Thin-walled cystic metastasis with peripheral uptake at the right upper lobe
 5. Hypermetabolic subcarinal lymph nodes

6. Right lower lobe with multiple thin-walled cystic metastasis
 7. Small left upper lobe pneumothorax chamber
 8. Hypermetabolic left hilar lymph node
 9. Left lower lobe
 10. Diffusely increased uptake in the left ventricular wall
 11. Thin-walled cystic metastasis with peripheral uptake at the left lower lobe

1.2.11 Case 11

A 43-year-old male patient, currently smoker, who presented with persistent productive cough with occasional drops of blood. ^{18}F -FDG PET/CT was performed, finding multiple metabolically active solid nodules with random distribution in both lungs, with two dominant lesions at the right lung, one of them with central cavitation. Ultrasound-

guided endobronchial biopsy confirmed the diagnosis of primary pulmonary melanoma at the right upper lobe, with multiple bilateral metastases. Additionally, a metastatic mediastinal lymph node conglomerate with necrotic components was found involving levels 7, 10R, and 11R, as well as a right neck level II metabolically active lymph node (Figs. 22 and 23) [27].

Figs. 22 and 23 1. Right upper lobe hypermetabolic cavitated nodule
 2. Mediastinal lymph node conglomerate with uneven uptake due to necrosis
 3. Trachea

 20. Right lower lobe
 21. Left lower lobe
 22. Right neck level II lymph node metastasis

1.2.12 Case 12

A 74-year-old woman with significant weight loss. Chest X-ray showed a mediastinal mass, so ^{18}F -FDG PET/CT was performed. Images revealed a high metabolically active left hilar mass with multiple mediastinal and lower neck metastatic lymph nodes, as well as a retroperitoneal lymph node. The diagnosis of a primary lung cancer was suggested, but transbronchial biopsy confirmed a diffuse, large B-cell lymphoma.

Findings that favor the diagnosis of lymphoma include the presence of a bulky mass with bulky lymph nodes, which surrounds or encases the bronchial and vascular structures, without compressing or invading them. Also, the presence of lymph nodes in other locations can give a clue, although there is no definitive finding to differentiate them from metastasis of a primary lung tumor (Fig. 24) [28].

 18. Common pulmonary artery
 19. Left main bronchus
 20. Spinal cord

1.2.13 Case 13

A 75-year-old female patient with history of breast cancer and recent diagnosis of small cell lung cancer, in treatment with immunotherapy (atezolizumab). Follow-up ^{18}F -FDG PET/CT showed increased size of metabolically active primary tumor in the left upper lobe, with a peripheral area of necrosis, as well as increased activity in two lesions that

were previously not so evident, one in the left diaphragmatic crus and other in the right perirenal area. At this time, the possibility of a pseudo-progression due to the ongoing treatment was considered, which was confirmed with the following follow-up, where metabolic response of all the described lesions was observed (Fig. 25) [29].

Fig. 25 1. Metabolically active primary tumor in the left upper lobe. Note the posterior necrotic component of the mass in the follow-up study

2. Right main bronchus
3. Left main bronchus
4. Small amount of left pleural effusion
5. Left mastectomy post-op changes
6. Increased activity at nodular lesion in the right perirenal space
7. Thoracic vertebral body osteophyte

17. Spinal canal
18. Right diaphragmatic crus
19. Caudate lobe
20. Left hepatic lobe
21. Increased activity at nodular lesion in the left diaphragmatic crus

1.2.14 Case 14

A 59-year-old woman with a history of breast cancer 25 years ago. She attended due to progressive dyspnea and chest radiograph showed diffuse opacity of the left lung, so ^{18}F -FDG PET/CT was performed. Images showed marked increased activity in diffuse nodular pleural thickening of the left lung, with involvement of the major fissure; there was no

significant pleural effusion or mediastinal lymph nodes. Pleural mesothelioma was initially suspected, but biopsy confirmed the diagnosis of pleural metastases from breast carcinoma. Although it is not the most frequent site of metastasis, the pleura can be the only manifestation of recurrent disease in up to 40% of cases (Fig. 26) [30].

Fig. 26 1. Marked increased activity at diffuse left pleural nodular thickening
2. Increased activity at left major fissure involvement
3. Increased activity at the deep left costophrenic angle involvement

13. Abdominal aorta
14. Ascending colon
15. Trachea
16. Aortic arch

1.2.15 Case 15

A 54-year-old woman with dyspnea and fatigue for several months. Chest X-ray was performed, finding bilateral pleural effusion and cardiomegaly. Given the suspicion of pulmonary embolism, contrast-enhanced CT was performed, finding a soft tissue mass involving the right ventricle, superior

vena cava, and innominate veins, as well as mild pericardial effusion. ¹⁸F-FDG PET/CT was performed for whole body evaluation, observing moderate, diffuse, increased activity in the soft tissue lesion described in tomography. Final diagnosis was consistent with a superior vena cava angiosarcoma (Fig. 27) [23].

Fig. 27 1. Hypermetabolic angiosarcoma, right ventricle component

 5. Bilateral pleural effusion
 6. Left ventricle

7. Esophagus
 8. Hypermetabolic angiosarcoma, superior vena cava component
 9. Sternum
 10. Sphenoid sinus
 11. Nasopharynx
 12. Oropharynx

1.2.16 Case 16

A 34-year-old male patient with progressive odynophagia and night sweats. ^{18}F -FDG PET/CT was performed finding a metabolically active mass in the oropharynx, consistent with biopsy-confirmed diffuse, large B-cell lymphoma; no other hypermetabolic lesion suggestive of lymphoma involvement was found. However, two incidental cardiac findings were

found: (1) diffuse increase in FDG uptake at the right ventricular wall, secondary to pulmonary hypertension and (2) focal FDG uptake at the upper portion of the interventricular septum, protruding into the left ventricle. The last finding corresponds to an asymmetric or isolated septal hypertrophy, also known as interventricular septal bulge (Fig. 28) [31].

16. Asymmetric or isolated septal hypertrophy, also known as interventricular septal bulge

1.2.17 Case 17

An 18-year-old man with diagnosis of Hodgkin lymphoma with inguinal lymph nodes involvement, undergoing treatment with first-line chemotherapy. After the second cycle, follow-up ¹⁸F-FDG PET/CT was performed, where complete

resolution of the previously visualized lymph nodes was observed. However, as a new finding, increased activity was found at the aortic root, consistent with inflammatory changes (aortitis), more likely related to the established treatment (Fig. 29) [32].

Fig. 29 1. Diffusely increased activity at the aortic root
 2. Increased activity at the vocal cords
 3. Increased activity at the distal esophagus, probable esophagitis

 14. Descending aorta

1.2.18 Case 18

A 32-year-old man diagnosed with Hodgkin lymphoma with nodal involvement. ^{18}F -FDG PET/CT was performed for end-of-therapy follow-up, where complete resolution of previously identified lymph nodes was found, consistent with metabolic complete response. However, increased activity

was found in the bilateral neck, supraclavicular fossae, and thoracic paravertebral areas, corresponding in the CT to fat with no underlying lesion. This finding represents metabolically active adipose tissue or brown fat and is a common finding specially related to cold temperatures (Fig. 30) [33].

 25. Pulmonary hilum

1.2.19 Case 19

A 71-year-old man with progressive fatigue, weight loss, and dyspnea, as well as fever in the last 3 weeks. Chest X-ray and CT did not show any remarkable findings, so ¹⁸F-FDG PET/CT was performed to rule out occult malignancy. Images showed multiple hypermetabolic mediastinal lymph nodes in paratracheal and bilateral hilar areas, as well as markedly increased activity in the enlarged spleen. Widespread FDG uptake was noted in both lungs without any CT abnormality. Transbronchial lymph node biopsy confirmed the diagnosis of diffuse, large B-cell lymphoma. Although the initial bron-

choalveolar lavage only showed increased alveolar macrophages, without evidence of abnormal lymphocytes, in the follow-up study all pulmonary findings disappeared as did the lymph nodes and splenomegaly. There are some cases with similar lung findings reported in the literature, where the histopathologic diagnosis of intravascular large B-cell lymphoma has been confirmed with the presence of large atypical lymphocytes in the lumina of the capillary vessels, so in this case, these findings and their evolution most likely represent lymphoma involvement (Fig. 31) [34].

1.2.20 Case 20

A 62-year-old woman with a history of Takayasu arteritis, who consulted for acute thoracoabdominal pain. Other possible causes of pain were ruled out, and ^{18}F -FDG PET/CT was performed to assess disease activity and thus define treatment. Images showed generalized increased activity in

the walls of the thoracoabdominal aorta, with involvement of the main cervical trunks, the iliac bifurcation, and the proximal iliac arteries. These findings indicate an active acute phase of the disease. No areas of stenosis or aneurysmal dilatation were observed (Fig. 32) [35].

1.2.21 Case 21

A 52-year-old male patient with a known diagnosis of Langerhans cell histiocytosis (LCH). After almost 2 years asymptomatic, he presented with lower back pain, so imaging studies including ^{18}F -FDG PET/CT were performed. Images showed diffusely increased activity in a perimetative and aggressive lytic lesion involving the left iliac bone and

sacral ala, as well as a smaller lesion with same characteristics in the right iliac bone; both lesions corresponded to LCH involvement. Additionally, minimal diffuse increased uptake was observed in both lungs, with multiple small irregular cystic lesions and septal thickening, with findings also corresponding to LCH involvement (Fig. 33).

1.3 Abdomen and Pelvis

1.3.1 Case 1

A 73-year-old man with a history of occasional dysphagia and weight loss. Upper digestive tract endoscopy showed suspicious findings of malignancy, so ^{18}F -FDG PET/CT was

performed. Images showed focal increased activity at the distal third of the esophagus in a concentric solid mass, which was later confirmed to correspond to a squamous cell carcinoma. No abnormal lymph nodes or distant metastasis were noted (Fig. 34) [14, 36].

1.3.2 Case 2

A 26-year-old female patient with occasional chest pain and reflux. Chest X-ray showed a mediastinal mass, so ¹⁸F-FDG PET/CT was performed, finding markedly increased activity in a prominent wall-based mass at the distal esophagus, with

exophytic growth and no lumen obstruction or mucosal involvement. The diagnosis of a gastrointestinal stromal tumor (GIST) was considered as the first possibility, which was later confirmed with biopsy (Fig. 35) [36].

1.3.3 Case 3

A 49-year-old man with chronic upper abdominal pain and weight loss. Endoscopic evaluation and biopsy were performed, finding an advanced gastric adenocarcinoma, so ^{18}F -FDG PET/CT was performed for staging. Images showed

increased metabolic activity in the gastric fundus and body at irregular wall thickening, consistent with the primary tumor. Metabolically active enlarged lymph nodes at the gastro-hepatic and right retrocrural areas were also noted (Figs. 36 and 37) [16].

Figs. 36 and 37 1. Metabolically active gastric wall thickening: primary gastric adenocarcinoma

 12. Left adrenal gland

1.3.4 Case 4

A 54-year-old male patient with weight loss and night sweats during the last 2 months. ^{18}F -FDG PET/CT was performed on suspicion of malignancy, where a bulky metabolically active mass was found in the stomach, as well as multiple

prominent hypermetabolic retroperitoneal lymph nodes. With these findings, a lymphoma was suggested, and the subsequent biopsy confirmed the diagnosis: diffuse, large B-cell lymphoma (Fig. 38) [37].

14. Abdominal aorta

1.3.5 Case 5

A 79-year-old woman with acute abdominal pain and vomiting. Contrast-enhanced CT was performed, finding a partial low-grade bowel obstruction with transition zone at the distal ileum. After managing the acute condition, ^{18}F -FDG PET/

CT was performed, finding a metabolically active concentric mass at the distal ileum with lumen reduction, without adjacent mesenteric fat stranding or other findings. Surgical resection was performed, confirming a primary large B-cell lymphoma (Fig. 39) [37].

1.3.6 Case 6

A 38-year-old man who attended an annual checkup completely asymptomatic. Colonoscopy and biopsy revealed a colon adenocarcinoma. ^{18}F -FDG PET/CT was performed for

staging, finding a focal increased activity in the distal transverse colon corresponding to the primary tumor, as well as a metabolically active mesenteric lymph node metastasis. No distant metastases were noted (Fig. 40) [13].

 13. Accessory spleen

1.3.7 Case 7

A 52-year-old woman with a history of constipation and occasional rectal bleeding. ¹⁸F-FDG PET/CT was performed to rule out malignancy. Images showed focal increased activity at the sigmoid colon suggesting a polypoid lesion.

Colonoscopy and biopsy were performed confirming the diagnosis of sigmoid colon adenocarcinoma. No abnormal hypermetabolic lymph nodes or metastasis were detected (Fig. 41) [13].

 17. Left piriformis muscle

1.3.8 Case 8

A 60-year-old man with a history of occasional rectal bleeding worsened in the last 2 weeks. Clinical examination and rectoscopy were performed and confirmed the presence of a mass, so ^{18}F -FDG PET/CT was performed. Images showed a

focal increased activity in the lower rectum at the primary tumor site, with no other hypermetabolic lesions suggesting metastasis. Final biopsy confirmed an adenocarcinoma (Fig. 42) [13].

1.3.9 Case 9

A 71-year-old man with a history of ascending colon adenocarcinoma 2 years ago, treated with laparoscopic right hemicolectomy and chemotherapy. He attended due to nodular feeling at the umbilical port scar where ultrasound showed a suspicious mass, so ¹⁸F-FDG PET/CT was performed.

Images showed a metabolically active spiculated lesion involving the subcutaneous tissue and both rectus abdominis muscles. Biopsy confirmed the presence of metastatic adenocarcinoma, probably secondary to a seeding during prior surgery (Fig. 43) [38].

1.3.10 Case 10

A 52-year-old male patient with persistent abdominal discomfort and occasional fever. Initial work-up showed high Ca19-9 (2540 units/ml), so contrast-enhanced CT and ^{18}F -FDG PET/CT were performed. Images showed focal increased activity in the pancreatic body, at a well-defined

hypovascular mass on CT, with distal pancreatic duct dilatation and parenchymal atrophy, which are typical findings of adenocarcinoma. Vascular involvement, lymph nodes, and distant metastases were excluded. Endoscopic ultrasound-guided biopsy confirmed the diagnosis of adenocarcinoma (Fig. 44) [15].

12. Pancreatic duct dilatation and parenchymal atrophy distal to the tumor
13. Abdominal aorta

1.3.11 Case 11

A 67-year-old man with abdominal pain who attended the emergency department. Abdominal ultrasound was performed finding slight dilation of the biliary tree and multiple focal liver lesions, suspicious of metastasis; the gallbladder was filled with sludge. Given the suspicion of a liver or pan-

creatic neoplasm, ¹⁸F-FDG PET/CT was indicated. Images showed a hypermetabolic mass in the gallbladder fundus with adjacent hepatic parenchyma involvement and multiple liver and lymph node metastases. The diagnosis of primary gallbladder carcinoma was later confirmed (Fig. 45) [15].

 19. Descending colon
 20. Left perirenal fat

1.3.12 Case 12

An 82-year-old man with known diagnosis of hepatocellular carcinoma treated with transarterial radioembolization. During follow-up, alpha-fetoprotein (AFP) was rising, so ^{18}F -FDG PET/CT was performed in order to evaluate the amount of remaining viable tumor. Images showed a prominent mass in the right hepatic lobe without significant FDG uptake, isometabolic to the liver parenchyma, with heteroge-

neous enhancement due to central areas of necrosis and posterior dystrophic calcifications related to treatment. FDG uptake in this type of tumors is highly variable and is determined by low expression of GLUT1 transporters, high activity of FDG-6-phosphatase and high expression of P-glycoprotein mainly, which also depend on tumor grade (Fig. 46) [39].

13. Posttreatment calcifications

1.3.13 Case 13

A 91-year-old female patient who attended the emergency department for abdominal pain. Abdominal ultrasound was performed, finding a heterogeneous mass in the left hepatic lobe, so ^{18}F -FDG PET/CT was performed. Images showed a mild metabolically active tumor in the left hepatic lobe, cor-

responding to the primary tumor, as well as multiple metastatic lymph nodes and peritoneal involvement with ascites and diffuse hypermetabolism in peritoneal fat stranding with nodularity. Biopsy confirmed the diagnosis of cholangiocarcinoma (Fig. 47) [15].

Fig. 47 1. Mild hypermetabolic mass in the left hepatic lobe: cholangiocarcinoma

 13. Increased uptake at stressed paraspinal muscles
 14. Left kidney inferior pole
 15. Perihepatic ascites

1.3.14 Case 14

A 48-year-old patient with abdominal pain and elevated Ca19-9. Abdominal ultrasound showed slight dilatation of the common bile duct and posterior endoscopic ultrasound-guided fine needle aspiration (FNA) biopsy confirmed the diagnosis of a small, distal, common bile duct adenocarcinoma; ^{18}F -FDG PET/CT was performed for staging. Images showed moderate diffuse increased activity surrounding the biliary drain, without any discernible macroscopic lesion. This increased uptake is due to attenuation correction artifacts with high-density material, and it is important to recognize it to avoid false-positive results (Fig. 48) [40].

Fig. 48 1. Attenuation correction artifact related to biliary drainage

 18. Left iliac crest

1.3.15 Case 15

A 38-year-old man with a known diagnosis of IgG4-related disease. He attends his routine control, asymptomatic, finding serum IgG4 levels slightly elevated so ^{18}F -FDG PET/CT was performed to monitor the underlying disease. Images showed diffuse FDG uptake in the pancreas, without peri-

pancreatic fat stranding or fluid collections, consistent with chronic autoimmune pancreatitis. Additionally, both submandibular glands showed increased uptake compared with the parotid glands, suggestive of chronic inflammation related to IgG4 deposits (Fig. 49) [41].

Fig. 49 1. Increased activity in bilateral submandibular glands
 2. Metabolically active, left, level II lymph node

1.3.16 Case 16

A 71-year-old male patient with history of inoperable pancreatic cancer under treatment with systemic chemotherapy. He attended an early checkup with abdominal pain, so ^{18}F -FDG PET/CT was performed. Images showed interval meta-

bolic response of the primary tumor with no definite uptake; however, new diffusely increased activity was noted in diffuse peritoneal fat stranding with nodularity and ascites, representing peritoneal spread of the tumor (Fig. 50) [42].

Fig. 50 1. Diffusely increased activity in peritoneal fat stranding with nodularity

 12. Left renal sinus

1.3.17 Case 17

A 28-year-old man with a history of diffuse, large B-cell lymphoma, with complete metabolic response 1 year earlier. He attended an early checkup due to a growing abdominal mass and night sweating. ¹⁸F-FDG PET/CT was initially

performed due to suspected lymphoma recurrence, finding splenomegaly with mild, diffuse, increased activity, as well as a focal hypermetabolic lesion. Small hypermetabolic retroperitoneal lymph nodes were also noted, so lymphoma recurrence was confirmed (Fig. 51).

Fig. 51 1. Splenomegaly with diffuse hypermetabolism as well as a focal hypermetabolic lesion

 16. Pancreatic body
 17. Portal vein

1.3.18 Case 18

A 20-year-old man with fever, fatigue, and gingival bleeding. Laboratory tests revealed low levels of white blood cells, red blood cells, and platelets, so a lymphoproliferative disease was suspected. Contrast-enhanced CT and ^{18}F -FDG PET/CT were performed and images showed hepatosplenomegaly and two small, hypometabolic, hypodense, poorly defined

splenic lesions with increased FDG uptake. No other findings, especially lymphadenopathy, were identified. Subsequently, a bone marrow biopsy was performed, reaching the final diagnosis of hemophagocytic lymphohistiocytosis. Treatment with dexamethasone was carried out, and 2 weeks later, follow-up studies were completely normal (Fig. 52) [43].

1.3.19 Case 19

A 5-year-old girl with pain and palpable mass in the left hemiabdomen. Abdominal ultrasound showed a left renal mass, so contrast-enhanced CT and ^{18}F -FDG PET/CT were performed. Images showed uneven increased activity in a prominent, well-defined mass at the lower pole of the left kidney, with heterogeneous contrast enhancement due to the presence of necrosis. The lesion showed the “claw sign”, representing how the normal parenchyma wraps the mass forming sharp angles with it, which confirms its renal origin

and the diagnosis of Wilms tumor over neuroblastoma, which is one of the most frequent tumors at this age. Other features favoring the diagnosis in this case are the well-defined margins, displacement of adjacent organs and structures without invasion, and the absence of retroperitoneal lymphadenopathies. Neuroblastoma is usually larger, crosses the midline, and is less defined, encasing vascular structures and sometimes invading the spinal canal; it is also associated with lymph nodes and metastases with greater frequency (Fig. 53) [44].

Fig. 53 1. Metabolically active left renal mass with necrosis: Wilms tumor

1.3.20 Case 20

A 73-year-old man with a 3-month history of hematuria. Renal ultrasound was performed, finding a suspicious mass in the left kidney, so contrast-enhanced CT and ^{18}F -FDG PET/CT were performed. Images showed mild, diffuse,

increased activity at the left kidney primary tumor, corresponding to a renal cell carcinoma, as well as hypermetabolism in the lumen of the enlarged left renal vein, consistent with a tumor thrombus. No distant metastases were observed (Fig. 54) [45].

Fig. 54 1. Mild hypermetabolic left renal cell carcinoma
 2. Metabolically active tumor thrombus in the left renal vein

 12. Right renal artery
 13. Left perirenal fat
 14. Left renal artery

1.3.21 Case 21

A 77-year-old female patient scheduled for retinal surgery. In the pre-surgical studies, blood count showed as an incidental finding, elevated leukocyte count with atypical cells. Bone marrow biopsy confirmed the diagnosis of diffuse, large B-cell lymphoma. ^{18}F -FDG PET/CT was performed for

staging, finding diffusely increased activity in a soft-tissue infiltration of the right perirenal space, without a definite mass. The right kidney morphology and parenchyma were completely preserved. Also, metabolically active retroperitoneal lymph nodes were observed (Fig. 55) [46].

Fig. 55 1. Diffusely increased activity at soft-tissue infiltration of the right perirenal space, corresponding to lymphoma involvement

 15. Hypermetabolic retroperitoneal paraaortic lymph node
 16. Left perirenal fat, normal appearance
 17. Abdominal aorta
 18. Mesenteric vessels

1.3.22 Case 22

A 71-year-old male patient with persistent hematuria and ultrasound documented left hydronephrosis. Ureteroscopy was performed, finding a solid mass in the middle portion of the left ureter, so ^{18}F -FDG PET/CT was performed. Images showed markedly increased activity at the middle third of the

left ureter, in a soft tissue mass, corresponding to biopsy-confirmed urothelial carcinoma, obstructing and leading to proximal dilatation and renal parenchymal atrophy. Periureteral fat stranding and small metabolically active lymph nodes around the mass were also noted (Fig. 56) [47].

11. Hyperdense oral contrast in the descending colon

1.3.23 Case 23

A 64-year-old female patient with history of right renal cell carcinoma, treated with partial nephrectomy and chemotherapy 2 years ago. She attended a routine checkup, where abdominal CT reported postoperative changes with a small

residual collection in the right perirenal space. When performing the complementary ¹⁸F-FDG PET/CT, focal nodular increased activity was noted at the postsurgical changes, later confirmed as tumor recurrence. No other hypermetabolic metastases were found (Fig. 57) [45].

Fig. 57 1. Focal increased activity at postsurgical changes in the right perirenal space and lateroconal fascia

 15. Small bowel mesentery
 16. Left psoas muscle

1.3.24 Case 24

A 54-year-old male patient with history of stage III lung adenocarcinoma, treated with external radiation therapy and posterior surgery. A routine chest CT reported partial visualization of a left adrenal lesion, so ^{18}F -FDG PET/CT was per-

formed. Images showed increased metabolic activity in the diffusely enlarged left adrenal gland, corresponding to a newly developed infrequent-shaped metastasis. No other hypermetabolic lesions were observed (Fig. 58).

14. Abdominal aorta
15. Right psoas muscle
16. Left anterior superior iliac spine

1.3.25 Case 25

A 64-year-old man with a history of diffuse, large B-cell lymphoma, treated 2 years ago with complete metabolic response, and a history of prostate cancer treated with surgery and radiotherapy 1 year ago. He attended hematology checkup with a follow-up ^{18}F -FDG PET/CT, where multiple slightly hypermetabolic lymph nodes were found in

the right internal and external iliac chains, as well as multiple moderately hypermetabolic bone lesions in thoracic and lumbar vertebral bodies, in both pelvic bones and the right femur. Subsequently, a PSA of 40 ng/ml was found and metastatic disease from an aggressive prostate cancer was confirmed with biopsy (Fig. 59) [48].

13. Left iliac wing sclerotic metastasis without FDG uptake

1.3.26 Case 26

A 46-year-old woman with occasional abdominal pain and suspected lymphoma due to a retroperitoneal lesion described in abdominal ultrasound. Contrast-enhanced CT and ^{18}F -FDG PET/CT were performed to confirm the diagnosis and stage the disease. Images showed focal increased activity at

an irregular thickening of the soft tissues surrounding the abdominal aorta just below the renal hilum, encasing it without compression. Subsequent biopsy confirmed an initial stage of retroperitoneal fibrosis and when carrying out extension studies, IgG4-related disease was confirmed as its etiology (Fig. 60) [49].

1.3.27 Case 27

A 79-year-old man with persistent fever and night sweats. Initial studies showed low white blood cell count and elevation of serum lactate dehydrogenase (LDH), so ¹⁸F-FDG PET/CT was performed to confirm and stage the diagnosis of lymphoma. Images showed multiple hypermetabolic medi-

astinal lymph nodes and a bulky retroperitoneal aortocaval lymph node conglomerate at the level of the renal hilum, as well as markedly increased activity in a right perirenal mass involving the perirenal fascia. Subsequent biopsy of the right perirenal mass confirmed the diagnosis of diffuse, large B-cell lymphoma (Fig. 61).

 16. Lumbar spinous process

1.3.28 Case 28

A 70-year-old woman with a growing abdominal mass and fever. Ultrasound-guided biopsy of the mass confirmed the diagnosis of germinal center B-cell (GCB) diffuse large B-cell lymphoma (DLBCL), so ^{18}F -FDG PET/CT was performed for staging. Images showed a bulky hypermetabolic mass with a central area of necrosis, surrounding the abdominal aorta below the renal hilum, as well as two small meta-

bolically active lymph nodes in the right pelvis and minimal, diffuse, increased uptake in the spleen (greater than that of the liver). DLBCL is the most common type of non-Hodgkin lymphoma and there are two main biological subtypes to consider, GCB, like in this patient, and activated B-cell (ABC) subtypes, the latter with a more aggressive behavior and worse prognosis. Other less frequent subtypes include double-hit and double-expressor lymphomas (Fig. 62) [50].

1.3.29 Case 29

A 44-year-old man with a history of acute myeloid leukemia (AML), treated 1 year ago. He attended an early checkup with a left cervical mass, so ^{18}F -FDG PET/CT was performed. Images showed multiple metabolically active lesions including a prominent left submandibular mass, multiple left

neck, mediastinal and retroperitoneal lymph nodes, nodular lesions at the right lung, stomach, pancreas and left kidney, as well as diffuse infiltration of the abdominal aorta wall. Biopsy of the cervical mass was performed and the diagnosis of myeloid sarcoma (MS), as an AML relapse, was confirmed (Fig. 63) [51].

1.3.30 Case 30

A 5-year-old girl who attended the emergency room for pelvic pain. They performed abdominal ultrasound identifying a complex pelvic mass, so contrast-enhanced CT and ^{18}F -FDG PET/CT were performed. Images showed diffusely increased activity in a prominent pelvic mass with heterogeneous

enhancement, displacing the bladder and invading the uterus and adnexa. The lesion was removed and the diagnosis of rhabdomyosarcoma was confirmed. Pelvic location is rare and almost exclusive in the pediatric population; in girls, the vagina is the most frequently involved organ (Fig. 64).

1.3.31 Case 31

A 67-year-old female patient with abnormal uterine bleeding. Gynecological ultrasound reported a heterogeneous uterine mass and to rule out malignancy vs fibroma with degenerative changes, so ¹⁸F-FDG PET/CT was performed. Images showed a prominent uterine mass with markedly

increased activity and central necrosis, involving the peri-uterine soft tissues, which was later confirmed to correspond to endometrial stromal sarcoma. Multiple hypermetabolic pelvic and retroperitoneal lymph nodes were also noted (Figs. 65 and 66) [52].

1.3.32 Case 32

A 62-year-old woman with abnormal vaginal bleeding and perineal pain. On physical examination, an ulcerated vulvar mass was found and excisional biopsy confirmed the diagnosis of carcinoma. They requested ^{18}F -FDG PET/CT for whole body evaluation. Images showed markedly focal

increased activity at the uterine cavity in posteriorly confirmed primary endometrial carcinoma, as well as two focal hypermetabolic lesions in the vaginal wall, corresponding to infrequent carcinoma metastases, just as the previously removed vulvar lesion (Fig. 67).

1.3.33 Case 33

A 57-year-old female patient with occasional abdominal pain, who attended a general checkup, with elevated CA 125. Gynecological ultrasound revealed a mixed solid and cystic mass, so contrast-enhanced CT and ^{18}F -FDG PET/CT were performed. Images showed a large complex pelvic mass

originated in the right ovary, with increased activity in the peripheral solid enhancing component, highly suspicious of malignancy. No other hypermetabolic lesions were detected. Later biopsy confirmed the diagnosis of a clear cell carcinoma (Fig. 68) [53].

1.3.34 Case 34

A 51-year-old woman with a history of gastric cancer treated with total gastrectomy and chemotherapy. She attended an early checkup due to abdominal pain and distension, so contrast-enhanced CT and ¹⁸F-FDG PET/CT were performed. Images showed diffusely increased activity at a prominent pelvic mass with solid and cystic components,

with thick enhancing septa, dependent on the left ovary. There was also increased activity at the enlarged and heterogeneous right ovary, as well as diffuse FDG uptake in pelvic ascites. Given the suspicion of metastasis, the lesions were surgically resected and the presence of signet ring cells, consistent with a Krukenberg tumor, confirmed the diagnosis (Fig. 69).

1.3.35 Case 35

A 57-year-old woman with abdominal distention and elevated tumor markers (CA125: 5138 and HE4: 212). Abdominal ultrasound revealed a complex pelvic mass and ascites, so an ovarian cancer was suspected and ^{18}F -FDG PET/CT was suggested. Images showed diffuse increased activity at the irregular pelvic mass with heterogeneous

enhancement involving both adnexal regions, as well as in ascites and sub-hepatic peritoneal seeding. The final diagnosis was bilateral ovarian cancer, high-grade serous carcinoma. Additionally, hypermetabolic mediastinal and left internal mammary lymph nodes were found, corresponding to uncommon metastases (Fig. 70) [53].

17. Ascites

18. Right piriformis muscle

1.3.36 Case 36

A 51-year-old woman with pelvic pain and vaginal discharge. Gynecological ultrasound showed an elongated complex solid-cystic lesion in the left adnexal region, suspicious of hydrosalpinx. However, tumor markers were elevated (CA125: 2130 and HE4: 162), so ^{18}F -FDG PET/CT and contrast-enhanced CT were performed. Images showed marked increased activity in the left adnexal region at an

irregular elongated lesion with heterogeneous enhancement, as well as small amounts of fluid within the endometrial cavity and the cul-de-sac. With these findings, malignancy was suspected, so the lesion was resected, and the pathology revealed a primary salpingeal carcinoma with ovarian involvement. These are extremely infrequent tumors originated in the fallopian tubes which account for less than 1.1% of gynecologic tumors (Fig. 71) [54].

1.3.37 Case 37

A 69-year-old man with progressive testicular pain and swelling. Ultrasound demonstrated bilateral diffuse enlargement of the testes with ill-defined hypoechoic signal, so lymphoma was suspected. ^{18}F -FDG PET/CT was performed for

staging, finding focal increased activity in both testes and in multiple mediastinal and retroperitoneal enlarged lymph nodes, as well as in diffuse peritoneal involvement. Subsequent biopsy confirmed the diagnosis of diffuse, large B-cell lymphoma (Fig. 72) [4].

1.4 Musculoskeletal System

1.4.1 Case 1

A 71-year-old male patient, ex-smoker, with diagnosis of a right solitary pulmonary nodule. ^{18}F -FDG PET/CT was performed, finding focal increased activity in the nodule (later

confirmed adenocarcinoma) and a single metastatic mediastinal lymph node. As an incidental finding, diffuse, increased uptake was observed in a fusiform soft tissue structure at the left scapular region, which represents physiological uptake in the Teres minor muscle, associated with probable muscle stress due to FDG injection (Fig. 73) [55].

18. Hypermetabolic metastatic mediastinal lymph node

1.4.2 Case 2

A 54-year-old man with small erythematous nodular lesion on the right anterior chest wall. Biopsy was performed and the final diagnosis was a non-upper aerodigestive tract (NUAT) extranodal natural killer T-cell lymphoma (NTCL), so ^{18}F -FDG PET/CT was performed for staging. Images showed focal increased activity at nodular lesions in the right

anterior chest wall, the left elbow, and the right vastus medialis muscle. No other cutaneous lesions or enlarged lymph nodes and splenic or bone marrow involvement were identified. This type of lymphoma is frequent in Asia and with its counterpart – UAT (upper aerodigestive tract) lymphoma which can be nasal or extranasal – it represents 10.5% of all non-Hodgkin lymphomas (Fig. 74) [56].

1.4.3 Case 3

A 59-year-old man with a right mid-back painful and growing mass. X-ray was performed finding a right rib expansive sclerotic lesion, so ¹⁸F-FDG PET/CT was performed suspecting malignancy. Images showed a metabolically

active expansive lesion at the right fifth rib posterior arc, with wide transition zone, chondroid matrix, and soft tissue involvement. Posterior biopsy confirmed a primary chondrosarcoma (Fig. 75).

1.4.4 Case 4

A 24-year-old female patient with diagnosis of non-Hodgkin lymphoma with cervical nodal involvement, undergoing end-of-therapy control. She reported mild back pain as the only symptom. ^{18}F -FDG PET/CT was performed, finding complete resolution of previously identified hypermetabolic

lymph nodes. However, as a new finding, symmetric FDG uptake was observed in the thoracic and lumbar spinal roots, as well as accumulation of the tracer in the thecal sac. The findings corresponded to neurolymphomatosis, a rare manifestation of non-Hodgkin lymphoma due to nerve infiltration by neurotrophic neoplastic cells (Fig. 76) [57].

1.4.5 Case 5

A 17-year-old man with acute right shoulder pain after trauma lifting weights in the gym. X-ray and MRI were performed, finding a pathological fracture of the right clavicle, so ^{18}F -FDG PET/CT was done. Images showed

increased activity at the middle third of the right clavicle in the site of the fracture, with a subjacent osteolytic lesion; no other hypermetabolic lesions were noted. Posterior biopsy confirmed the diagnosis of a primary osteosarcoma (Fig. 77) [58].

1.4.6 Case 6

A 37-year-old woman with a history of right breast cancer, treated with neoadjuvant chemotherapy and subsequent surgery. She attended an early checkup due to back pain, and an initial bone scan suggested new vertebral metastases. ^{18}F -

FDG PET/CT was performed finding, in addition to vertebral metastases, other small hypermetabolic lesions in both pelvic bones and the right proximal femur, which were not evident in bone scan (Fig. 78).

Fig. 78 1. Metabolically active thoracic and lumbar vertebral bodies metastases
 2. Multiple hypermetabolic metastases in both pelvic bones and right femur

1.4.7 Case 7

A 61-year-old man with a history of meningeal hemangiopericytoma resection 6 years ago. He attended an early checkup due to lower back and hip pain, so ¹⁸F-FDG PET/CT was performed. Images showed multiple metabolically active lytic bone lesions with soft tissue mass component at the skull base, ribs, thoracic and lumbar vertebral bodies, and both pelvic bones, as well as mediastinal and retroperitoneal lymph nodes. Focal lesions in the liver, the soft tissues of the

right scapular region, and the right gluteal region were also noted. Biopsy, performed at the left iliac bone lesion, confirmed the diagnosis of metastatic anaplastic hemangiopericytoma. This is a rare mesenchymal tumor that can affect bone structures and soft tissues anywhere in the body. Currently, it is known to share genetic and histological characteristics with solitary fibrous tumors, so this aggressive and disseminated behavior is expected (Fig. 79) [59].

 22. Small bowel loops
 23. Normal activity at both ureters

1.4.8 Case 8

A 64-year-old woman with a recent diagnosis of multiple myeloma, with few lytic lesions evident in conventional radiology studies but marked generalized bone pain. ^{18}F -FDG PET/CT was performed to assess the distribution and activity of the disease. Images showed innumerable hypermeta-

bolic lesions involving the whole axial and proximal appendicular skeleton, most of them lytic, but others expansive with soft tissue components in the ribs and vertebral bodies. With these findings, it was possible to determine that it was an active and disseminated form of myeloma, and treatment was started (Fig. 80) [6, 60].

22. Left sacroiliac joint

1.4.9 Case 9

A 42-year-old man with lower back pain and a lytic lesion on conventional radiography. ¹⁸F-FDG PET/CT was performed for evaluation and images showed a prominent mass in the right hemiabdomen with a hypermetabolic peripheral solid component and central necrosis. The mass was clearly arising from the neural foramen and had a small component in

the medullary canal, displacing the spinal cord (“dumbbell sign”). With these findings, a peripheral nerve sheath tumor was suspected and considering its large size, the associated bone destruction, and the necrotic component, malignancy was suggested. Subsequent biopsy of the lesion confirmed the diagnosis of a malignant peripheral nerve sheath tumor (Fig. 81) [61].

 10. Spinal cord

1.4.10 Case 10

A 25-year-old man with a history of brachial plexus peripheral nerve sheath tumor, treated with wide excision and nerve graft 2 years ago. He attended an early checkup because of left hip pain, and X-ray showed a pathological fracture of the iliac bone, so ^{18}F -FDG PET/CT was performed. Images showed

intense increased activity at a soft tissue mass surrounding the left iliac wing with a pathological fracture. Another smaller lesion but with the same characteristics was found in the soft tissues of the left ninth intercostal space. Posterior biopsies confirmed the diagnosis of malignant peripheral nerve sheath tumor in both locations (Figs. 82 and 83).

Figs. 82 and 83 (continued)

1.4.11 Case 11

A 43-year-old man complaining of left hip pain with decreased range of motion. Hip X-ray showed slightly diffuse disturbance of the trabecular pattern in the left iliac bone, so ^{18}F -FDG PET/CT was performed to rule out malignancy.

Images showed minimal, diffuse, increased activity in the left iliac bone, where on CT, small osteolytic lucent areas were observed with some coarsened trabeculae. The findings correspond to early-phase changes of Paget's disease (Fig. 84).

 11. Sacrum

1.4.12 Case 12

A 75-year-old man with a rapidly growing painful mass in the right leg. ¹⁸F-FDG PET/CT was performed, finding markedly increased activity at a rounded, well-defined soft

tissue mass in the right thigh, involving the external obturator and adductor longus muscles. Biopsy confirmed the suspected diagnosis of an undifferentiated pleomorphic sarcoma (UPS) (Fig. 85) [62].

 17. Scrotum
 18. Right pectineus muscle

1.4.13 Case 13

A 27-year-old man with a non-painful growing mass in the left thigh. Ultrasound showed a solid soft tissue mass, so ^{18}F -FDG PET/CT was performed. Images showed diffuse and homogeneously increased activity at a well-defined, hypodense oval mass in the posterior aspect of the left thigh,

with displacement of the adjacent muscles without infiltration. With these characteristics, the diagnosis of a myxoid liposarcoma was suspected, which is the second most frequent subtype of liposarcoma, and at this age, the extremities are the most frequent location. The diagnosis was confirmed later with biopsy (Fig. 86) [62].

19. Normal right popliteal Lymph node

1.4.14 Case 14

A 36-year-old man with a growing mass in the right gluteal region. Hip X-ray did not show any bone abnormality, but US revealed a heterogeneous and infiltrating mass, so ^{18}F -FDG PET/CT and MRI were performed. Images showed mild, diffuse, increased activity in an oval, well-defined mass

at the right gluteal region, involving the gluteus maximus and medius muscles at their insertion, with heterogeneous signal intensity on T2WI, mainly hyperintense. Subsequent biopsy confirmed the diagnosis of low-grade synovial sarcoma, which explains the mild FDG uptake (Fig. 87) [62].

1.4.15 Case 15

A 28-year-old woman with a history of Ewing's sarcoma in the left iliac bone, treated with hemipelvectomy and radiotherapy. Twelve years later, she attended an early checkup for pelvic pain, so ^{18}F -FDG PET/CT was performed. Images

showed a poorly defined and infiltrating lytic lesion at the sacrum and the right iliac bone, with increased peripheral multifocal activity. Biopsy of the lesion confirmed the diagnosis of radiation-induced osteosarcoma (Fig. 88) [63].

6. Bladder
7. Right sacroiliac joint

1.4.16 Case 16

A 66-year-old man with a history of rectal adenocarcinoma treated with surgery and adjuvant chemotherapy. Follow-up chest CT showed multiple new lymphadenopathies, so ^{18}F -FDG PET/CT was performed to rule out disease progression. Images showed increased activity in multiple mediastinal lymph nodes at peritracheal, prevascular, and hilar areas, as well as in few retroperitoneal lymph nodes. Additionally,

multiple linear foci of increased FDG uptake were found in the muscles of both upper limbs, lumbar region, gluteal regions, and thighs. Subsequent biopsy of one of the muscle lesions confirmed the diagnosis of sarcoidosis. Muscular involvement in sarcoidosis can be detected in random biopsy in up to 80% of cases; however, it is usually underdiagnosed because symptoms only present in less than 3% of patients (Fig. 89) [64].

1.4.17 Case 17

An 80-year-old woman with chronic pain in the left knee, without a history of trauma. X-ray showed an aggressive sclerotic lesion in the distal femur, so ^{18}F -FDG PET/CT was performed. Images showed marked increased activity in an extensive intramedullary bone lesion at the distal femur, compromising the diaphysis, metaphysis, and epiphysis,

with a dense bone matrix, a narrow transition zone and without significant periosteal reaction or soft tissue involvement. No skip lesions or distant metastases were found. Subsequent biopsy confirmed the diagnosis of osteosarcoma. Joint effusion with diffuse FDG uptake was also found in the suprapatellar bursa (Fig. 90).

2 Non-FDG PET/CT

2.1 ¹⁸F-Fluciclovine PET/CT

2.1.1 Case 1

A 68-year-old man with a history of prostate cancer treated with radical prostatectomy and radiotherapy. He attended routine control with a biochemical relapse, so ¹⁸F-fluciclovine PET/CT was performed, finding focal increased activity in

the surgical bed behind the bladder, consistent with recurrent tumor. This new radiotracer, a synthetic analog of the amino acid L-leucine, has the main advantage that the activity in the excreted urine is minimal or null, which allows the detection of lesions in the surgical bed with high precision, as in this case. Additionally, it has been shown that it allows the detection of small lesions with high diagnostic accuracy (Fig. 91) [65, 66].

2.1.2 Case 2

A 55-year-old man with a history of prostate cancer treated with radical prostatectomy and radiotherapy. He presented biochemical relapse and conventional images did not show any suspicious lesions of local recurrence or metastasis, so ^{18}F -fluciclovine PET/CT was performed. Images showed

focal increased uptake in small metastatic lymph nodes at both iliac chains, which, due to their size, had been considered reactive in conventional images. As previously mentioned, one of the advantages of this new radiotracer is the detection of small lesions with high sensitivity and specificity (Fig. 92) [65, 66].

2.2 ⁶⁸Ga-DOTA TOC PET/CT

2.2.1 Case 1

A 38-year-old patient with a history of secondary hyperparathyroidism due to a parathyroid adenoma, 1 year earlier. On routine follow-up, fasting hypoglycemia and elevated chromogranin A were found, so ⁶⁸Ga-DOTA-TOC PET/CT was performed suspecting a pancreatic neuroendocrine tumor. Images showed multifocal increased activity in the body and

tail of the pancreas, as well as two focal hypermetabolic liver lesions and increased size of both adrenal glands with diffuse uptake. The diagnosis of a grade 2 pancreatic neuroendocrine tumor was later confirmed, and the other lesions were consistent with liver metastasis, right adrenocortical hyperplasia, and left adrenal adenoma. With these findings and the previous diagnosis of parathyroid adenoma, additional studies were carried out confirming the diagnosis of multiple endocrine neoplasia type 1 (MEN1) (Fig. 93) [67].

Fig. 93 1. Multifocal increased activity at the pancreatic body and tail; insulinoma

 15. Left kidney inferior pole

2.2.2 Case 2

A 65-year-old woman with a history of occasional headaches. Outside CT reported a left temporal mass and she was referred for evaluation with the suspected diagnosis of a meningioma. ^{68}Ga -DOTA-TOC PET/MR was performed,

finding a metabolically active left temporal extra-axial well-defined mass, with broad dural base, consistent with a typical meningioma. Contrast-enhanced MRI showed marked and homogeneous enhancement (Fig. 94) [68].

9. Left optic nerve

2.2.3 Case 3

A 51-year-old female patient with progressive behavior and personality changes. Contrast-enhanced brain MRI was performed, finding a prominent enhancing extra-axial, dural-based, well-defined mass involving both frontal lobes. A ⁶⁸Ga-DOTA-TOC PET/MR was performed, confirming a

metabolically active meningioma. Additionally, the presence of small hypermetabolic spinal and right parietal leptomeningeal seeding was found, which is characteristic of atypical meningioma, with more aggressive behavior (Figs. 95 and 96) [68].

 13. Left rib, posterior arc
 14. Spinous process

2.2.4 Case 4

A 52-year-old woman with a history of breast cancer. During initial staging, contrast-enhanced brain MRI was performed finding a well-defined, bilobulated, dural-based mass involving both occipital lobes. In order to differentiate between a

meningioma and metastasis, ⁶⁸Ga-DOTA-TOC PET/MR was performed, as this is one of its indications. The avid uptake of the mass confirmed the diagnosis of meningioma and the patient did not require any additional management (Fig. 97).

 9. Cerebellum

2.2.5 Case 5

A 71-year-old man who attended an annual routine checkup. Esophagogastroduodenoscopy was performed identifying a small nodular lesion in the proximal duodenum and biopsy confirmed the diagnosis of a grade 1 neuroendocrine tumor, so ^{68}Ga -DOTA-TOC PET/CT was performed. Images showed focal increased activity in the duodenal bulb, where a small nodular lesion with marked enhancement in the arte-

rial phase was identified on CT, corresponding to the primary tumor; no hypermetabolic liver lesions were identified. As an additional finding, there was focal increased FDG uptake in a small right thyroid nodule, corresponding to a known adenomatous nodule. Note normal tracer uptake in the liver, spleen, kidneys, pituitary, adrenal glands, salivary glands, bowel, and prostate gland (Fig. 98) [67].

2.3 ⁶⁸Ga-NOTA Glu-Urea-Lys (NGUL) PET/CT

2.3.1 Case 1

⁶⁸Ga-NOTA Glu-urea-lys (NGUL) study in a 60-year-old male patient diagnosed with prostate cancer and treated with radical prostatectomy and chemotherapy. The follow-up study with this novel prostate-specific membrane antigen

(PSMA) targeting tracer shows normal distribution at lacrimal glands, parotid and submandibular glands, mediastinal blood pool, liver, spleen, and urinary system. Studies have shown that compared with ⁶⁸Ga-PSMA-11, the most widely used tracer, ⁶⁸Ga-NGUL shows lower uptake in normal organs and a trend of relatively low tumor-to-background ratio (Fig. 99) [69].

Fig. 99 1. Physiologic uptake in lacrimal glands

2. Physiologic uptake in parotid glands

2.4 ^{11}C -Acetate PET/CT

2.4.1 Case 1

A 56-year-old male patient with left flank pain. A left renal mass was found on CT and biopsy revealed a renal cell carcinoma. ^{11}C -acetate PET/CT was performed for initial stag-

ing. Images demonstrated moderate increased activity at the primary tumor in the left kidney, as well as in a right adrenal gland metastasis and multiple LNs metastases in both retrocrural areas and retroperitoneum, metastatic (Figs. 100 and 101) [70].

Fig. 100 1. Pancreas
2. Metabolically active metastasis in the right adrenal gland
3. Hypermetabolic retrocrural lymph node metastases

Fig. 101 1. Hypermetabolic retroperitoneal lymph nodes metastases
 2. Metabolically active left renal cell carcinoma

2.4.2 Case 2

A 69-year-old woman attended her routine health checkup, where a lung nodule was found on a chest X-ray. ^{11}C -acetate PET/CT was done for differential diagnosis, and images

showed increased activity in the partly solid lung nodule at the right lower lobe, which was proved to be an adenocarcinoma after surgery (Figs. 102 and 103) [70].

Fig. 102 1. Left ventricle
2. Mild metabolically active, right, lower lobe adenocarcinoma

Fig. 103 1. Pancreas, physiologic activity
2. Liver, physiologic activity

2.5 ^{11}C -Methionine PET/CT

2.5.1 Case 1

A 5-year-old boy with dizziness and vomiting. A brain tumor was suspected on CT and MRI, so ^{11}C -methionine PET/CT

was performed for differential diagnosis. Images demonstrated focal increased activity in a right cerebellar mass, which was later proved to be a pilocytic astrocytoma (WHO grade I) (Figs. 104 and 105) [70].

Fig. 104 1. Mild uptake in pituitary gland (physiologic uptake)
2. Brain tumor in right cerebellum (pathology: pilocytic astrocytoma)

Fig. 105 1. Intense uptake in lacrimal gland (physiologic uptake)
2. Cerebellum

2.5.2 Case 2

A 14-year-old male patient with frequent vomiting, tremor, and recent memory loss. Brain MRI showed multiple masses, so ¹¹C-methionine PET/CT was performed for char-

acterization. Images showed focal increased uptake in a suprasellar irregular mass with peripheral calcifications, which was confirmed to be a germ cell tumor, as suspected (Figs. 106 and 107).

Fig. 106 1. Metabolically active suprasellar germ cell tumor
2. Interpeduncular fossa

3. Midbrain

Fig. 107 1. Metabolically active suprasellar germ cell tumor

2.6 ^{11}C -PIB PET/CT

2.6.1 Case 1

A 66-year-old woman attended for dementia work-up. ^{11}C -PIB PET/CT was done demonstrating normal findings

which include diffusely increased uptake in the white matter and no definite uptake in the gray matter (Figs. 108 and 109) [71].

Fig. 108 1. Frontal lobe, gray matter
2. Frontal lobe, white matter
3. Lateral ventricle

4. Temporal lobe, white matter
 5. Lateral ventricle

2.6.2 Case 2

A 71-year-old female showed memory loss symptoms. ¹¹C-PIB PET/CT was performed on a suspicion of dementia and

images showed diffusely increased uptake in the gray matter and basal ganglia, which are consistent with the diagnosis of Alzheimer’s disease (Figs. 110 and 111) [71].

Fig. 110 1. Frontal lobe, gray matter
2. Frontal lobe, white matter

3. Parietal lobe, white matter

2.7 ^{18}F -FP-CIT PET/CT

2.7.1 Case 1

A 66-year-old male patient suffering from tremor for 2 months. ^{18}F -FP-CIT PET/CT was performed, finding

marked increased uptake in the caudate nucleus, putamen, and midbrain. The patient was diagnosed with essential tremor (Figs. 112 and 113) [72].

Fig. 112 1. Head of caudate nucleus
2. Putamen + globus pallidus

Fig. 113 1. Putamen + globus pallidus
2. Lateral ventricle

2.7.2 Case 2

A 54-year-old male patient with a known diagnosis of Parkinson's disease, who underwent ^{18}F -FP-CIT PET/CT in routine checkup. Images showed decreased activity in the

bilateral putamina, mainly in the dorsal portion, which are the characteristic findings of Parkinson's disease (Figs. 114 and 115) [72].

Fig. 114 1. Caudate nucleus
2. Putamen (decreased uptake)

Fig. 115 1. Head of caudate nucleus
 2. Putamen (decreased uptake in dorsal portion)
 3. Lateral ventricle, posterior horn

2.8 ¹⁸F-Flumazenil PET/CT

2.8.1 Case 1

A 39-year-old man with a history of epilepsy diagnosed during childhood, who underwent a ¹⁸F-flumazenil PET/CT for

follow-up. Images showed normal findings which consist of diffusely increased uptake in the cerebral cortex and relatively mildly increased uptake in the basal ganglia (Figs. 116 and 117) [70].

Fig. 116 1. Caudate nucleus
2. Lateral ventricle

Fig. 117 1. Temporal cortex
 2. Midbrain
 3. Occipital cortex

2.9 ⁶⁸Ga-Arginine-Glycine-Aspartic Acid (RGD) PET/CT

2.9.1 Case 1

A 50-year-old female patient with biopsy proven breast cancer. ⁶⁸Ga-arginine-glycine-aspartic acid (RGD) PET/CT was

done for staging. Images showed focal increased activity in the left breast at the primary tumor, as well as in an enlarged LN at the left axillary level I. These lesions were confirmed as infiltrating ductal carcinoma and metastatic LN. Mild uptake was found in the right thyroid gland, which was proved to be a benign nodule (Figs. 118 and 119) [73].

Fig. 118 1. Metabolically active left breast cancer
2. Myocardium, left ventricle

Fig. 119 1. Hypermetabolic LN metastasis in the left axillary level I
2. Descending aorta

2.10 ¹⁸F-Florbetaben PET/CT

2.10.1 Case 1

¹⁸F-florbetaben-PET/CT represents a very important diagnostic tool for the diagnosis and follow-up of patients with Alzheimer's disease, which is used to estimate β -amyloid plaque deposits. Visual assessment, which has a high sensi-

tivity and specificity, is made according to the differential uptake between gray matter and white matter. When the differentiation is preserved, as in the figure on the left, a normal study is considered. However, when the differentiation is not clear and there is diffuse uptake in the gray matter, as the figure in the right, the presence of β -amyloid deposits is confirmed (Fig. 120) [70].

 15. Fourth ventricle
 16. Choroid plexus calcification at the right lateral ventricle
 17. Septum pellucidum

2.11 ¹⁸F-Florastamin PET/CT

2.11.1 Case 1

A 64-year-old man with a history of prostate cancer, currently in biochemical relapse. ¹⁸F-florastamin PET/CT was performed for further evaluation, finding multiple prostate-specific membrane antigen (PSMA) avid metastatic lymph

nodes in the neck, mediastinum, retroperitoneum and iliac chains, as well as bilateral lung and liver metastasis. Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein overexpressed in prostate cancer cells. Multiple radiolabeled molecules that bind to it, such as ¹⁸F-florastamin, have emerged and currently represent the diagnostic standard for prostate cancer diagnosis (Fig. 121) [74].

 19. Left kidney

2.12 ^{18}F -FDOPA PET/CT

2.12.1 Case 1

A 47-year-old woman with diagnosis of multiple endocrine neoplasia type 2 (MEN2) who underwent an ^{18}F -FDOPA PET/CT during follow-up. Images showed focal increased activity in both thyroid lobes, where suspicious heterogeneous nodules were identified on CT and US. Total thyroidectomy and lymph node dissection were performed, with a final diagnosis of bilateral medullary thyroid carcinoma (Fig. 122).

2.12.2 Case 2

A 31-year-old woman who consulted for abnormal sweating, dizziness, and occasional palpitations. At physical examination she was hypertensive, so the diagnosis of pheochromocytoma was suspected and ^{18}F -FDOPA PET/CT was performed for evaluation. Images showed marked increased activity in a left adrenal mass with heterogeneous enhancement in contrast images due to the presence of necrosis, with typical findings of a pheochromocytoma (Fig. 123).

2.13 ¹⁸F-Choline PET/CT

2.13.1 Case 1

A 44-year-old man who attended an annual checkup finding elevated PSA (9.53 ng/ml). Digital rectal examination was normal, as well as prostate volume (36 cc). However, multi-parametric MRI showed a 2 cm PI RADS 5 lesion on the

right side of the peripheral zone. Posterior biopsy confirmed the diagnosis of adenocarcinoma and an ¹⁸F-choline PET/CT scan was performed for staging. Images showed focal increased activity in the right peripheral zone at the primary tumor location. No metabolically active metastases were noted (Fig. 124) [70, 66].

Atlas and Anatomy of SPECT/CT

E. Edmund Kim, Vanessa Murad, Jin-Chul Paeng,
Hyung-Jun Im, Ji-Young Kim, and Gi-Jeong Cheon

Single-photon emission computed tomography (SPECT) imaging has evolved rapidly during the past decades since the introduction of the Anger camera in 1970, the posterior rotating gantry and dual detectors with better reconstruction processes, and quantitative data analysis. In the late 1990s, hybrid SPECT/CT imaging appeared to improve diagnostic accuracy with precise anatomical location and image quality with attenuation correction. In the last 10 years, the improvements in this equipment and the evolution in radiopharmaceuticals have allowed us to improve in the evaluation of physiological processes and in the characterization of pathologies based on morphological patterns [1]. Conventional analog technologies have advanced to multidetector devices with direct conversion digital detectors that improve efficiency, resolution and image quality, resulting in faster studies with lower doses and even the ability to image multiple radionuclides simultaneously. This includes the last generation cadmium-zinc-telluride (CZT) scanners, which bring more

possibilities in research and clinical practice, especially in nuclear cardiology [2–4]. There is no denying that SPECT is still the go-to choice for most cardiologists.

There are multiple SPECT/CT applications, and in this chapter, we introduce most of them with demonstrative examples. In tumor pathology, its best-known applications are the evaluation of bone tumors, especially osteoblastic metastases, neuroendocrine tumors, and parathyroid adenomas [5, 6]. However, there are other multiple uses such as the evaluation of hepatocellular carcinoma, liver metastasis, neuroblastoma, paraganglioma, and thyroid cancer. In non-tumor bone pathology, it is indicated in trauma, degenerative disease, and infection, for example – also in the evaluation of benign thyroid pathology, gastrointestinal bleeding, lymphatic system pathology, and pulmonary physiology, among others [5, 7–9]. SPECT systems as well as radiopharmaceuticals are more available and probably cost-effective than PET, so they remain and will remain at the forefront.

1 Tumors

1.1 Hepatocellular Carcinoma

1.1.1 Case 1

A 51-year-old man with a diagnosis of hepatocellular carcinoma. Selected SPECT (*top*) and SPECT/CT (*bottom*) of the

liver with ^{99m}Tc -MAA particles injected into a hepatic arterial catheter showed several focal areas of slightly to moderately increased activity in the right and left hepatic lobes corresponding to multicentric hepatoma. Only 50% of hepatomas can be imaged with FDG-PET, mainly because of the high levels of phosphatase that dephosphorylate FDG and allow it to diffuse out of cells (Fig. 1) [10].

Fig. 1 ^{99m}Tc -MAA SPECT/CT

1.2 Liver Metastases

1.2.1 Case 1

A 68-year-old female patient with liver metastasis from breast cancer. Selected SPECT (*top*) and SPECT/CT (*bot-*

tom) of the liver with ^{99m}Tc-MAA into the hepatic arterial catheter showed markedly heterogeneous activity in the liver caused by known metastases. There was no extra hepatic activity (Fig. 2) [11].

Fig. 2 ^{99m}Tc-MAA SPECT/CT

1.2.2 Case 2

Selected SPECT (*top*) and SPECT/CT (*bottom*) of the upper abdomen with ^{99m}Tc-MAA particles into a hepatic arterial

catheter showed curvilinear activity along the gastric wall, indicating the suboptimal position of the hepatic arterial catheter (Fig. 3) [12].

Fig. 3 ^{99m}Tc-MAA SPECT/CT

1.2.3 Case 3

A 57-year-old female patient with hepatic metastasis of breast cancer. Selected SPECT (*top*) and SPECT/CT (*bottom*) images of the liver with ⁹⁰Y microspheres injected into

a hepatic arterial catheter showed increased activity in the right and left hepatic lobes, corresponding to metastatic lesions (Fig. 4) [13].

Fig. 4 ⁹⁰Y SPECT/CT

1.3 Neuroendocrine Tumors

1.3.1 Case 1

A 51-year-old male patient with chest tightness and dyspnea. He had prior history of a pancreatic neuroendocrine tumor,

so ^{111}In -octreotide SPECT/CT was done. Images showed focal increased activity in a soft tissue mass at the pericardium, which was posteriorly confirmed to be a metastatic lesion (Fig. 5) [14].

5. Liver
6. Sternum

7. Left ventricle
8. Metastasis in pericardium
9. Left lower lobe of lung
10. Descending aorta
11. Left kidney

1.3.2 Case 2

A 72-year-old male patient with a history of midgut carcinoid. He attended with right shoulder and abdominal pain. ¹¹¹In-octreotide SPECT/CT was performed, finding focal

increased activity in the right glenoid at a sclerotic lesion and the right hepatic lobe at a large necrotic mass. Posterior biopsy confirmed the diagnosis of metastatic neuroendocrine tumor (Fig. 6) [15].

Fig. 6 1. Right subscapularis muscle
 2. Metastasis in right scapula neck
 3. Right supraspinatus muscle
 4. Right humerus
 5. Right clavicle

6. Left pectoralis minor muscle
 7. Left pectoralis major muscle
 8. Vertebral body
 9. Liver metastasis with central necrosis

1.3.3 Case 3

A 71-year-old male patient with abdominal pain, diarrhea, and elevated chromogranin A. ¹¹¹In-octreotide SPECT/CT was performed, finding marked increased activity in a large

pancreatic tail mass, as well as diffuse, increased activity in the portal vein. Surgical resection confirmed the diagnosis of a pancreatic neuroendocrine tumor with portal vein invasion (Fig. 7) [16].

 4. Neuroendocrine tumor in the portal vein
 5. Liver, S6

6. Liver, S5
 7. Liver, S4
 8. Liver, S1
 9. Stomach
 10. Spleen

1.3.4 Case 4

A 62-year-old female patient with a history of midgut carcinoid. She presented with cough, dyspnea, and abdominal pain, so ¹¹¹In-octreotide SPECT/CT was done. Images showed a large mass in the right adrenal gland without

abnormal increased activity. Also, diffuse, increased activity was noted in a consolidation at the right upper lung. Posterior biopsy of both lesions confirmed a right adrenal carcinoma and a metastatic neuroendocrine tumor in the right upper lung (Fig. 8) [17].

Fig. 8 1. Aortic arch
 2. Vertebral body
 3. Neuroendocrine tumor in RUL

4. Trachea
 5. Right adrenal cancer

1.3.5 Case 5

A 54-year-old female patient with a history of rectal carcinoma. She developed abdominal pain and elevated serum levels of chromogranin A were found. ¹¹¹In-octreotide

SPECT/CT was performed, finding multifocal increased uptake in the right hepatic lobe at several biopsy confirmed metastasis (Fig. 9) [18].

Fig. 9 1. Left kidney
2. Vertebral body
3. Right kidney

4. NE tumor in liver S6
5. NE tumor in liver S5
6. Abdominal aorta

1.3.6 Case 6

A 74-year-old female patient with abdominal pain and diarrhea. ¹¹¹In-octreotide SPECT/CT was done, finding

focal increased activity in the pancreatic head. The surgical diagnosis was a pancreatic neuroendocrine tumor (Fig. 10) [21].

Fig. 10 1. Spleen
2. Abdominal aorta
3. Liver

4. Gallbladder
5. NE tumor in pancreatic body
6. Stomach

1.3.7 Case 7

A 67-year-old male patient with hypertension, abdominal pain, and palpitations. Elevated urinary catecholamines were

found, so ^{123}I -MIBG SPECT/CT was performed. Images showed focal increased uptake in a left adrenal mass which was confirmed as a pheochromocytoma (Fig. 11) [22].

2. Abdominal aorta
3. Liver, S6
4. Liver, S5

5. IVC
6. Portal vein
7. Stomach
8. Left adrenal pheochromocytoma

1.3.8 Case 8

A 68-year-old female patient with a history of midgut carcinoid developed chest pain and dyspnea. Chest X-ray showed a newly developed lung nodules and she had elevated

serum levels of chromogranin A, so ^{111}In -octreotide SPECT/CT was done. Images showed focal increased uptake in the right upper lung nodule, which was confirmed to be a metastatic neuroendocrine tumor (Fig. 12) [25].

Fig. 12 1. Left main bronchus
2. Right main bronchus
3. Rib
4. Neuroendocrine tumor metastasis in right lung

5. Ascending aorta
6. Pulmonary trunk
7. Descending aorta

1.3.9 Case 9

A 64-year-old female patient with a neuroendocrine tumor in the pancreatic tail. Selected SPECT (*top*) and SPECT/CT

(*bottom*) images of the upper abdomen with ¹¹¹In-octreotide showed a focal area of slightly increased activity in the pancreatic tail. No other lesions were observed (Fig. 13) [27].

Fig. 13 ¹¹¹In-octreotide SPECT/CT

1.3.10 Case 10

A 41-year-old male patient with a history of carcinoid tumor, who attended for a regular check-up. ¹¹¹In-octreotide SPECT/CT was done, finding focal increased activity in the middle

to lower abdomen corresponding to mesenteric lymph node metastases, as well as in two metastatic lesions in the right hepatic lobe (Fig. 14) [30].

Fig. 14 ¹¹¹In-octreotide SPECT/CT

1.3.11 Case 11

A 39-year-old male patient with biopsy-proven lung carcinoid, who underwent ¹¹¹In-octreotide SPECT/CT for stag-

ing. Images showed focal increased activity in the right hilum at the primary tumor, without definite uptake in post-obstructive atelectasis (Fig. 15) [32].

Fig. 15 ¹¹¹In-octreotide SPECT/CT

1.3.12 Case 12

A 51-year-old female patient with a biopsy confirmed diagnosis of transverse colon neuroendocrine tumor. ¹¹¹In-octreotide SPECT/CT was performed for staging, find-

ing only focal increased uptake in the primary lesion at the proximal transverse colon (Fig. 16) [33].

Fig. 16 ¹¹¹In-octreotide SPECT/CT

1.4 Neuroblastoma

1.4.1 Case 1

A 3-year-old girl with confirmed diagnosis of retroperitoneal neuroblastoma. ^{123}I -MIBG SPECT/CT was performed for further evaluation. Images showed focal increased uptake in a retroperitoneal mass adjacent to the left psoas muscle, cor-

responding to the primary tumor. Neuroblastoma is a neural crest cell tumor arising from the sympathetic chain, commonly in the adrenal gland, and the mean age at the diagnosis was 2 years. Metastases may be found in 75% of these patients. Meta-iodobenzylguanidine (MIBG) is similar to norepinephrine and is taken up by chromaffin granules that are in neuroblastoma and pheochromocytoma (Fig. 17) [35].

Fig. 17 ^{123}I -MIBG SPECT/CT

1.5 Paraganglioma

1.5.1 Case 1

A 59-year-old male patient, who attended with hypertension and perspiration. Elevated levels of urinary catecholamines were found, so ¹²³I-MIBG SPECT/CT was done for further

evaluation. Images showed focal increased activity in a retroperitoneal mass at the aortocaval space, as well as in the left kidney superior pole. The surgical diagnosis confirmed a primary renal paraganglioma with retroperitoneal metastasis (Fig. 18).

Fig. 18 1. Abdominal aorta
 2. Metastatic paraganglioma in aortocaval area
 3. IVC
 4. Right kidney

5. Liver, left lobe
 6. Pancreas
 7. Stomach
 8. Renal paraganglioma

1.5.2 Case 2

A 57-year-old female patient with a history of left adrenal paraganglioma, who attended for routine check-up. ¹²³I-MIBG SPECT/CT was performed, showing heterogeneous activity in the liver, with a focal nodular increased uptake in segment 5 (V). Heterogeneous activity in the liver

is physiologic and related to timing of the imaging and radiotracer metabolism and excretion through the biliary system. However, focal increased uptake is an abnormal finding, and in this case, it corresponded to a metastatic lesion. Also, an active metastasis was found in the T8 vertebral body (Fig. 19) [36].

Fig. 19 ¹²³I-MIBG SPECT/CT

1.6 Thyroid Cancer

1.6.1 Case 1

A 59-year-old male patient with a history of thyroid cancer, who underwent coronary CT, finding incidentally multiple

lung nodules. ^{131}I SPECT/CT showed moderately to intense increased iodine uptake in the nodules, confirming metastatic disease. Iodine therapy with 200 mCi of ^{131}I was administered (Figs. 20, 21, 22 and 23) [37].

 5. Right lower lobe (RLL) superior segment metastatic nodule

Fig. 23 1. Left lower lung lobe superior segment metastatic nodule
2. Left lower lung lobe lateral basal segment metastatic nodule

1.6.2 Case 2

A 34-year-old female patient with thyroid cancer, who underwent total thyroidectomy with central neck dissection. On ^{131}I ablation scan, bone metastases were found, which

were treated with 250 mCi of ^{131}I . Post-treatment iodine scan and SPECT/CT were taken, showing intense focal iodine uptakes at T4 and T6, confirming iodine-avid bone metastases (Figs. 24, 25, 26, 27, 28, and 29) [38].

9. Spleen

1.6.3 Case 3

A 62-year-old female patient with thyroid cancer history, who was treated with thyroidectomy 6 months earlier. She attended a routine follow-up without symptoms and normal serum levels of thyroglobulin. Selected SPECT (*top*) and

SPECT/CT (*bottom*) with ¹³¹I demonstrated a focal area of moderately increased activity in the left thyroid bed, which was confirmed to be residual functioning thyroid tissue (Fig. 30).

Fig. 30 ¹³¹I SPECT/CT

1.7 Parathyroid Adenoma

1.7.1 Case 1

A 63-year-old male patient with hypercalcemia and weight loss. Laboratory tests showed abnormal serum calcium,

phosphorus, and parathyroid hormone levels, so primary hyperparathyroidism was suspected. ^{99m}Tc -MIBI SPECT/CT was performed finding focal delayed uptake in the lower aspect of the right thyroid lobe, corresponding to a parathyroid adenoma, type E (Figs. 31, 32, 33, 34, and 35) [40, 41].

 9. Esophagus
 10. Spinous process of T3 spine

1.7.2 Case 2

A 63-year-old female patient with suspicion of parathyroid adenoma, who underwent ^{99m}Tc-MIBI SPECT/CT. Images

showed a focal area of moderately increased activity in the right lower anterior mediastinum, which was confirmed as a parathyroid adenoma, type F (Fig. 36) [42].

Fig. 36 ^{99m}Tc-MIBI SPECT/CT

1.7.3 Case 3

A 71-year-old female patient with primary hyperparathyroidism, who underwent ^{99m}Tc -MIBI SPECT/CT. Images showed a focal moderately increased activity in the right

paraesophageal area at the level of the thoracic inlet, which corresponded to a parathyroid adenoma, type F (Fig. 37) [42].

Fig. 37 ^{99m}Tc -MIBI SPECT/CT

1.7.4 Case 4

A 56-year-old male patient with confirmed diagnosis of a parathyroid adenoma (type E). Selected SPECT (*top*) and SPECT/CT (*bottom*) of the neck and chest with ^{99m}Tc-MIBI

were performed. Images showed a focal moderately increased activity in the right paratracheal area at the level of the right inferior thyroid bed (Fig. 38) [42].

Fig. 38 ^{99m}Tc-MIBI SPECT/CT

1.7.5 Case 5

A 63-year-old female patient with suspicion of a parathyroid adenoma (type C). Selected SPECT (top) and SPECT/CT images of the neck and chest with ^{99m}Tc -MIBI showed a

focal moderately increased activity in the right paraesophageal area, confirming the diagnosis (Fig. 39) [42].

Fig. 39 ^{99m}Tc -MIBI SPECT/CT

1.8 Mesothelioma

1.8.1 Case 1

A 69-year-old male patient with chest pain and dyspnea. The diagnosis of a mesothelioma was confirmed and ^{99m}Tc-MAA SPECT/CT was performed during staging. Images showed

slightly decreased activity in the right upper and middle lobes as well as moderately decreased activity in the right lower lobe. Also noted were perfusion defects along the posterolateral periphery of the right lower lobe owing to nodular pleural lesions (Fig. 40) [43].

Fig. 40 ^{99m}Tc-MAA SPECT/CT

1.9 Bone Tumors

1.9.1 Case 1

A 10-year-old girl with a history of ossifying fibroma, who underwent ^{99m}Tc -methylene diphosphonate (MDP) SPECT/CT during a follow-up. Images showed moderately increased

activity in the bilateral maxillary sinuses and right mandible at expansile bone lesions with fibrous matrix and peripheral sclerotic rim. Ossifying fibromas are benign bone tumors and occur often in children under 10 years in the tibia, femur, mandible, maxilla, and nasal areas (Fig. 41) [45].

Fig. 41 ^{99m}Tc -MDP SPECT/CT

1.9.2 Case 2

A 76-year-old male patient with lower back pain. ^{99m}Tc-MDP SPECT/CT showed focal increased uptake at bilateral L5-S1 facet joints, with degenerative changes. Additionally, a focal increased uptake was noted at the superior aspect of

the left iliac bone, corresponding to a non-aggressive bone lesion with a central hipodense nidus surrounded by sclerotic bone changes, which was confirmed to be an osteoid osteoma (Fig. 42).

1.10 Bone Metastases

1.10.1 Case 1

A 38-year-old female patient with a history of breast cancer, who attended with right shoulder pain. ^{99m}Tc-MDP SPECT/CT was done, finding focal moderately increased activity in the right scapular body, caused by metastasis. Bone metastases are over ten times more common than primary bone

tumors. Most metastases occur in the red bone marrow, most commonly in the axial skeleton. Osteoblastic metastases often occur with prostate cancer, transitional cell carcinoma, mucinous tumor, and carcinoid, whereas lytic metastases mostly occur with lung, thyroid, and renal cancers. Breast, stomach, and colon cancers can show osteolytic or osteoblastic lesions (Fig. 43) [46].

Fig. 43 ^{99m}Tc-MDP SPECT/CT

1.10.2 Case 2

A 65-year-old female patient with a history of breast cancer, who attended due to right knee pain without previous trauma. ^{99m}Tc-MDP SPECT/CT showed markedly increased activity

in the lateral posterior condyle of the right distal femur at a mixed lytic and blastic bone lesion, consistent with bone metastasis (Fig. 44).

Fig. 44 ^{99m}Tc-MDP SPECT/CT

1.10.3 Case 3

A 47-year-old female patient with a history of breast cancer presented with pain in the lower back. Selected SPECT (*top*)

and SPECT/CT (*bottom*) images of the pelvis with ^{99m}Tc-MDP showed markedly increased activity in the left sacral ala, abutting the sacroiliac joint (Fig. 45).

Fig. 45 ^{99m}Tc-MDP SPECT/CT

1.10.4 Case 4

A 66-year-old female patient with a history of non-Hodgkin lymphoma. She attended an early checkup due to lower back pain. ^{99m}Tc-MDP SPECT/CT was performed, finding focal

areas of slightly increased activity in the bilateral iliac alae and tuberosities as well as L3-S1 vertebral bodies. Biopsy confirmed active lymphoma involvement (Fig. 46).

Fig. 46 ^{99m}Tc-MDP SPECT/CT

2 Non-Tumorous Conditions

2.1 Bone

2.1.1 Case 1

A 71-year-old female patient with chronic right knee pain. The clinical diagnosis was a medial meniscus tear in the

right knee, and ^{99m}Tc -MDP SPECT/CT was done for further evaluation. Focal increased uptake was found in the right medial meniscus area, confirming the clinical diagnosis and associated changes in the subjacent bone (Figs. 47, 48, 49, and 50) [49].

2. Right tibial lateral condyle

Fig. 50 1. Tibial tuberosity
2. Active lesion at right medial meniscus
3. Tibial lateral condyle

4. Fibular articular facet
5. Fibular head

2.1.2 Case 2

A 56-year-old female with a history of breast cancer complained of pain in her right lower posterior chest after a fall. ^{99m}Tc-MDP SPECT/CT showed focal increased activity in the right posterior 11th rib, corresponding to a callus formation at a fracture seen on CT. An acute fracture (up to 3–4 weeks after initial injury) will show increased radio-

tracer uptake surrounding the fracture site. Ninety-five percent of fractures are positive in patients under 65 years old, but skull fractures rarely show activity. In the healing phase with a variable time course, there is a gradual decrease in radiotracer activity, but 40% of fractures remain abnormal after 1 year (Fig. 51) [50].

Fig. 51 ^{99m}Tc-MDP SPECT/CT

2.1.3 Case 3

A 65-year-old male patient with a history of lung cancer, who developed a backache following a car accident. ^{99m}Tc-MDP SPECT/CT showed a focal area of markedly increased

activity in the spinous process of L4, corresponding to a fracture shown on CT. Slightly increased activity in the bilateral facet joints of L4 was also noted, caused by degenerative changes (Fig. 52) [51].

Fig. 52 ^{99m}Tc-MDP SPECT/CT

2.1.4 Case 4

A 61-year-old female patient with chronic bilateral shoulder pain and limitation was admitted for evaluation. ^{99m}Tc -MDP SPECT/CT was performed, finding diffuse increased uptake

in the bilateral shoulder joint capsules and bony structures, which was consistent with adhesive capsulitis, more severe in the right shoulder (Figs. 53, 54, 55, and 56) [53].

5. Increased uptake in glenoid cavity
6. Scapula neck

2.1.5 Case 5

A 21-year-old male patient with bilateral temporomandibular joint pain. ^{99m}Tc -MDP SPECT/CT was performed, find-

ing increased uptake in both temporomandibular joints (right > left), due to degenerative osteoarthritis (Fig. 57).

9. Left mastoid air cells

2.1.6 Case 6

A 48-year-old male patient with right knee varus deformity treated with high tibial osteotomy. In the immediate postoperative period, ^{99m}Tc -MDP SPECT/CT was performed (*top*), finding, in addition to the normal changes of surgery, degenerative changes in the right knee with increased focal uptake in the femorotibial joint, more marked in the medial compartment, as well as in the patellofemoral joint. Three months

after surgery, the patient attended with mild pain in the right knee. A new study was carried out (*bottom*) where degenerative changes showed improvement, but as a new finding, an increased uptake was observed in one of the surgical screws at the proximal tibia. Normal reactive postoperative changes were considered as the first option; however, a short-term follow-up was recommended to rule out other complications, which were later discarded (Fig. 58).

13. Left fibula head

2.1.7 Case 7

A 16-year-old male patient with a history of leukemia, who developed left hip pain after completion of chemotherapy. ^{99m}Tc-MDP SPECT/CT showed a curvilinear moderately increased activity in the left femoral head at an ill-defined area of increased density on CT, caused by a healing microfracture with avascular necrosis (AVN). AVN is cellular

death of bone components caused by interruption of the blood supply. It often leads to destruction of the joint articular surface. The classic sites are the head of the femur, the neck of the talus, and the waist of the scaphoid. AVN initially shows decreased radiotracer activity in the affected region, followed by a hyperemic phase with increased uptake (Fig. 59) [55].

Fig. 59 ^{99m}Tc-MDP SPECT/CT

2.1.8 Case 8

A 20-year-old male patient with progressive low back pain, worsened by physical activity. ^{99m}Tc-MDP SPECT/CT was

performed and showed increased uptake in the inferior aspect of bilateral sacroiliac joints, without morphologic changes. The findings were consistent with sacroiliitis (Fig. 60).

2.1.9 Case 9

A 27-year-old male patient with right foot pain. ^{99m}Tc -MDP SPECT/CT was performed finding focal increased uptake in the medial aspect of the midfoot, adjacent to the medial side

of the navicular bone, at an accessory ossicle. These findings confirmed the diagnosis of accessory navicular syndrome (Fig. 61).

2.2 Others

2.2.1 Gastrointestinal Bleeding

2.2.1.1. Case 1

A 10-year-old male patient with anaplastic large B-cell lymphoma was suffering from hematochezia caused by acute

graft-versus-host disease (GVHD) after peripheral blood stem cell treatment. ^{99m}Tc-labeled red blood cell (^{99m}Tc-RBC) gastrointestinal bleeding SPECT/CT was done to find the bleeding source. A focal uptake was found in the third portion of the duodenum, corresponding to the acute bleeding site (Figs. 62, 63, 64, 65, 66, and 67) [56].

 8. Left external iliac vessels
 9. Rectovesical pouch
 10. Rectum

2.2.1.2. Case 2

A 68-year-old male patient with a history of cystectomy for bladder cancer. He developed pain in the right lower abdomen and also noticed bloody stool. ^{99m}Tc-RBC SPECT/CT demonstrated a curvilinear moderately increased activity in the ileal conduit as well as the pouch and bag indicating active bleeding. ^{99m}Tc-RBC is useful for detecting active gastrointestinal bleeding and is prepared in vitro by mixing 1–3 mL of anticoagulated blood with stannous chloride and

an oxidizing agent. The labeling procedure takes at least 20 minutes. Bleeding rates as low as 0.2 mL/min can be detected with a tagged red blood cell study compared to 1 mL/min for angiography. ^{99m}Tc-sulfur colloid requires a significant preparation time and is useful only for acute active bleeding with 2–3 minutes of vascular half-time. A positive study shows an activity that changes shape and position over time due to the peristalsis of intraluminal blood (Fig. 68) [57].

Fig. 68 ^{99m}Tc-RBC SPECT/CT

2.2.2 Abscess

2.2.2.1. Case 1

A 78-year-old female patient with a history of multiple myeloma, who attended for backache and fever. ¹¹¹In-WBC SPECT/CT showed a focal area of markedly increased activity in the left semispinalis muscle at the posterior lower neck adjacent to the spinous process of C6, corresponding to an ill-defined inflammatory collection. ¹¹¹In leukocyte, scan is

helpful for detecting acute infection or inflammation. Its advantages compared to ^{99m}Tc-D, L-hexamethyl propyleneamine oxime (HMPAO) scan include the absence of interfering bowel and renal activity and the ability to perform delayed 24-hour imaging as well as simultaneous ^{99m}Tc-sulfur colloid or MDP scan. ⁶⁷Ga citrate scan is useful for detecting chronic infection or inflammation with lymphocytes or macrophages (Fig. 69) [58].

Fig. 69 ¹¹¹In-WBC SPECT/CT

2.2.3 Benign Thyroid Pathology

2.2.3.1. Case 1

A 57-year-old female patient with a new diagnosis of hypothyroidism. ¹³¹I SPECT/CT showed a focal area of moderately increased activity in the midline of the tongue base, corresponding to ectopic thyroid tissue in the thyroglossal duct. Ectopic thyroid refers to the presence of thyroid tissue in locations other than the normal anterior neck between the second and fourth tracheal cartilages. Lingual thyroid is the most common type (Fig. 70) [59].

base, corresponding to ectopic thyroid tissue in the thyroglossal duct. Ectopic thyroid refers to the presence of thyroid tissue in locations other than the normal anterior neck between the second and fourth tracheal cartilages. Lingual thyroid is the most common type (Fig. 70) [59].

Fig. 70 ¹³¹I SPECT/CT

2.2.3.2. Case 2

A 32-year-old female patient with neck pain and fever. Thyroid function studies showed low TSH with increased T3 and T4, so subacute thyroiditis was suspected. ^{99m}Tc -

pertechnetate thyroid scan SPECT/CT was performed showing faintly visualized thyroid activity and decreased percentage of thyroid uptake (0.08%), so the diagnosis was confirmed (Fig. 71).

19. Hard palate
20. Sternum

2.2.3.3. Case 3

A 37-year-old female patient with known hyperthyroidism, Graves' disease, who attended her annual checkup. Thyroid function studies showed low TSH with increased T3 and T4,

and increased TSH-R-Ab. ^{99m}Tc -pertechnetate thyroid scan SPECT/CT was performed showing diffuse enlargement of the thyroid gland with markedly increased percentage of thyroid uptake (26.32%) (Fig. 72).

17. Lung apex

2.2.4 Salivary Glands

2.2.4.1. Case 1

A 63-year-old female patient with nonspecific sicca. ^{99m}Tc-pertechnetate salivary gland scan SPECT/CT with quantita-

tive analysis was performed and showed mild decreased uptake in bilateral parotid glands, with normal submandibular glands uptake, and normal bilateral function (Figs. 73 and 74).

Figs. 73 and 74 1. Parotid glands. The 20-minute scan shows bilateral mild decreased uptake, and the 40-minute scan shows complete excretion
 2. Submandibular glands. The 20-minute scan shows normal bilateral uptake, and the 40-minute scan shows complete excretion
 3. Radiotracer excretion in the oral cavity
 4. Thyroid gland, normal uptake

- 12. Left clavicle

2.2.5 Cerebrospinal Fluid (CSF)

2.2.5.1. Case 1

A 66-year-old male patient with a history of head trauma. Moderate enlargement of ventricular size was found on CT, so after ventricular derivation, selected SPECT (*top*) and

SPECT/CT (*bottom*) images of the head at 24 hours after injection of ¹¹¹In-DTPA into the L3-L4 spinal canal were obtained for evaluation. Images showed distribution in basal and Sylvian cisterns, without significant residual hydrocephalus or activity in the lateral ventricle, indicating non-communicating hydrocephalus (Fig. 75) [60].

Fig. 75 ¹¹¹In-DTPA SPECT/CT

2.2.5.2. Case 2

A 72-year-old male patient with progressive gait disturbance, urinary incontinence, and dementia symptoms. Selected SPECT (top) and SPECT/CT (bottom) images of the head at 24 hours after injection of ¹¹¹In-DTPA into the L3-L4 spinal

canal showed moderately increased activity in the lateral ventricles but no significant activity had migrated over to the convexity beyond the Sylvian cistern, indicating normal pressure hydrocephalus (Fig. 76).

Fig. 76 ¹¹¹In-DTPA SPECT/CT

2.2.6 Central Venous Line Obstruction

2.2.6.1. Case 1

A 46-year-old male with a left central venous line complained of pain in the substernal area. A nuclear dynamic venous flow study using ^{99m}Tc-DTPA showed a focal area of increased activity in the distal left innominate vein, repre-

senting obstruction. Venous obstruction occurs when blood clots or vascular tissues develop and narrow the channel for flow. More than 40% of patients with a central venous line can develop a venous obstruction, and they may experience a swollen arm, neck pain, facial swelling, or shortness of breath (Fig. 77) [61].

Fig. 77 ^{99m}Tc-DTPA SPECT/CT

2.2.7 Renal

2.2.7.1. Case 1

A 49-year-old male patient with right hydronephrosis due to renal pelvis stones. ^{99m}Tc -DTPA and SPECT/CT were per-

formed for evaluation, finding decreased uptake in the right kidney with no significant effect in renal function. Calculated GFR (ml/min): left 48.58, right 42.36 (Fig. 78).

Fig. 78 1. Right kidney, decreased uptake
2. Left kidney, normal uptake
3. Stomach

7. Right psoas muscle

8. Liver
9. Right sacral ala
10. Left sacroiliac joint
11. Left renal cortex
12. Left renal sinus
13. Descending colon

2.2.7.2. Case 2

A 72-year-old male patient with history of kidney transplant in 2015, who attended his annual checkup. ^{99m}Tc-DTPA and SPECT/CT were performed to find a normal functioning

transplanted kidney with calculated GFR (ml/min) of 96.78. Native non-functioning kidneys showed atrophy in the right side and a large water bag kidney in the left side (Fig. 79).

Fig. 79 1. Transplanted kidney in the right pelvis

 10. Gallbladder
 11. Inferior vena cava

2.2.8 Lymphatic System

2.2.8.1. Case 1

A 44-year-old woman with a history of right breast cancer treated with total mastectomy and axillary lymph node dissection, who developed right arm lymphedema. ^{99m}Tc -ASC

lymphoscintigraphy and SPECT/CT was performed and showed absence of main lymphatics in the right arm, as well as absence of lymph nodes and positive dermal backflow (DBF) until the elbow level. In the left arm, normal lymphatic vessels and lymph nodes were observed (Fig. 80).

Fig. 80 1. Injection site at both hands
2. Dermal backflow in the right arm
3. Mild increased activity in the liver
4. Left axillary lymph nodes
5. Normal main lymphatics in the left arm

6. Left distal humerus
7. Left arm subcutaneous tissue, normal appearance
8. Right ulna
9. Right radius

2.2.8.2. Case 2

A 45-year-old male patient with confirmed diagnosis of left preauricular melanoma. Selected SPECT (*top*) and SPECT/CT (*bottom*) images of the neck, including the lower head, after intradermal injection of ^{99m}Tc filtered sulfur colloidal particles around the tumor, demonstrated focal areas of slightly increased activity in the left upper jugular lymphatic

chain (level IIB), indicating sentinel lymph nodes. The sentinel lymph node is hypothetically the first lymph node or group of nodes to drain the cancer. It is postulated that sentinel lymph nodes are the target organs primarily reached by metastasizing cancer cells from the tumor. The spread of some forms of cancer usually follows an orderly progression (Fig. 81) [62].

Fig. 81 ^{99m}Tc-filtered sulfur colloid SPECT/CT

2.2.8.3. Case 3

A 59-year-old female patient with uterine cervical cancer. SPECT (*top*) and SPECT/CT (*bottom*) images of the pelvis after subcutaneous injection of ^{99m}Tc -filtered sulfur colloid

particles around the area were performed. Images showed moderate increased activity in the left external iliac lymph node and slightly increased activity in the left inguinal superficial lymph node, indicating sentinel lymph nodes (Fig. 82).

Fig. 82 ^{99m}Tc -filtered sulfur colloid SPECT/CT

2.2.8.4. Case 4

A 53-year-old female patient with recent diagnosis of melanoma in the right anterior chest wall. Selected SPECT (*top*) and SPECT/CT (*bottom*) images of the chest after intrader-

mal injection of ^{99m}Tc -filtered sulfur colloid showed a focal area of slightly increased activity in the right superficial axillary lymph node (level I), indicating a sentinel lymph node (Fig. 83).

Fig. 83 ^{99m}Tc -filtered sulfur colloid SPECT/CT

2.2.8.5. Case 5

A 64-year-old male patient with a squamous cell carcinoma in the right tongue base. Selected SPECT (*top*) and SPECT/CT (*bottom*) images of the neck, including the lower head, after subcutaneous injection of ^{99m}Tc Lymphoseek showed a

focal area of slightly increased activity in the right carotid space, indicating a sentinel lymph node. Lymphoseek is a radioactive diagnostic agent for lymphatic mapping and guiding sentinel lymph node biopsy (Fig. 84) [63].

Fig. 84 ^{99m}Tc -lymphoseek SPECT/CT

2.2.9 Lung (V/Q)

2.2.9.1. Case 1

A 58-year-old male patient with non-small cell lung cancer, adenocarcinoma. ^{99m}Tc-MAA SPECT/CT was performed, finding a non-uniform distribution of the particles, indicating

moderately decreased perfusion in the right upper, middle, and lower lobes. There was complete absence of particles within the tumor. ^{99m}Tc-MAA SPECT/CT is frequently performed for the presurgical evaluation of patients with lung cancer to determine the extent of surgery (Figs. 85, 86, and 87) [64, 65].

Fig. 85 ^{99m}Tc-MAA SPECT/CT

Fig. 86 ^{99m}Tc-MAA SPECT/CT

Fig. 87 ^{99m}Tc-MAA SPECT/CT

2.2.9.2. Case 2

A 26-year-old female patient with a history of recurrent respiratory papillomatosis, who developed a lung squamous cell carcinoma. Presurgical lung perfusion scan with SPECT/CT was performed to determine lung function and extent of

surgery. Images showed a spiculated dense nodule in the right lower lobe, corresponding to the primary tumor, as well as complete perfusion defect in the whole lobe, probably due to obstruction (Fig. 88).

2.2.10 Accessory Spleen

2.2.10.1. Case 1

A 50-year-old male patient attended a routine checkup and abdominal CT was performed finding an enhancing mass

adjacent to the pancreatic tail. ^{99m}Tc -denatured RBC spleen scan was done for differential diagnosis, finding focal increased uptake in the nodular lesion at the pancreatic tail, which corresponded to an accessory spleen (Figs. 89, 90, 91, and 92) [66].

2.2.11 Adrenal Hyperplasia

2.2.11.1. Case 1

A 52-year-old male patient with right flank pain and abnormal adrenal function tests. So ^{123}I -MIBG SPECT/CT was

performed for further evaluation. Images showed moderately increased activity in both adrenal glands, corresponding to adrenal hyperplasia. Also, a right renal mass was observed on CT, which was later confirmed to be a renal cell carcinoma (Fig. 93).

10. Spleen

2.2.12 Heart

2.2.12.1. Case 1

An 84-year-old male patient with a history of asymptomatic coronary atherosclerosis, who attended a routine checkup and referred occasional chest pain. Laboratory studies were

carried out finding increased troponin and proBNP, as well as increased free light chain of lambda and kappa (18.66 and 21.16, respectively). ^{99m}Tc-HMDP heart planar scan with SPECT/CT was performed and images showed significant heart uptake, which suggested transthyretin-related (TTR) amyloidosis, later confirmed with biopsy (Fig. 94) [67].

Fig. 94 1. Markedly increased uptake in the left ventricular wall: amyloidosis involvement
 2. Focal increased uptake in the right acromioclavicular joint: degenerative changes

 16. Stomach

2.2.13 Brain

2.2.13.1. Case 1

A 35-year-old asymptomatic man with diagnosis of Moyamoya disease who attended a periodic checkup. ^{99m}Tc -HMPAO brain perfusion SPECT was performed. Basal study

showed adequate perfusion in all vascular territories bilaterally. In post-acetazolamide study, perfusion is maintained and/or increased, which indicates that the vascular reserve is preserved. Anterior cerebral artery (ACA), middle cerebral artery (MCA), internal carotid artery (ICA = ACA + MCA), and posterior cerebral artery (PCA) (Fig. 95) [68].

Fig. 95 ^{99m}Tc -HMPAO brain perfusion SPECT

2.2.13.2. Case 2

An 84-year-old woman with a diagnosis of severe atherosclerotic carotid stenosis of both extracranial internal carotid arteries. ^{99m}Tc -HMPAO brain perfusion SPECT was performed to determine if there was surgical indication. Basal study showed adequate perfusion in all territories. However, the post-acetazolamide study showed decreased perfusion in

the left ICA (ACA + MCA) territory, indicating that the vascular reserve is compromised because the stenosis has progressed to the point of consuming compensatory capacity. These findings indicate that the patient would benefit from surgical intervention to prevent and/or reduce the risk of stroke (Fig. 96) [68].

Fig. 96 ^{99m}Tc -HMPAO brain perfusion SPECT

Index

A

Abdominal aorta, 26, 29, 130, 177
Abdominis rectus muscles, 113
Accessory spleen, 268, 271
Adrenal hyperplasia, 272
Alpha-fetoprotein (AFP), 65
Anterior junction line, 267
Anterior rectal wall leiomyoma, 37
Aortic knob, 88
Ascending aorta, 21, 22, 193
Ascending colon, 175
Avascular necrosis (AVN), 240
Azygos vein, 136

B

Basilar artery, 4–6, 151
B cell lymphoma, 63, 69, 71
Benign thyroid pathology, 253
Biceps femoris muscle, 49
Bladder, 142
Bone tumors, 222
Brain malignancy, 2

C

C5 right transverse process, 252
Caudate lobe, 34, 105
Caudate nucleus, 170
Caudate putamen, 165
Celiac trunk, 27
Central venous line obstruction, 257
Cerebellar vermis, 4, 5
Cerebellum, 5
Cerebrospinal fluid (CSF), 255
Cervical biopsy, 40
Cervical spinous process, 176
Cholangiocarcinoma (CCA), 29
Clivus, 60
Coccyx, 36, 178
Crista galli, 6

D

Descending aorta, 51
Diaphragmatic crura, 100
Diaphragmatic cupula, 144, 147
Displaced urinary bladder, 118
Distended stomach, 152
DNA synthesis, 1
Dyspnea, 81

E

Epiglottis, 14
Esophagus, 85, 124, 129
Ethmoid air cells, 4
Extra nodal marginal zone B-cell lymphoma (EMZBC), 6

F

Falciform ligament, 153
Falx cerebri, 56
Fatigue, 81
Femoral shaft, 49
¹⁸F-fluciclovine, 145
18F-Fludeoxyglucose (FDG), 1
Fibula shaft, 47
Foramen magnum, 60
Frontal lobe, gray matter, 164
Frontal lobe, white matter, 164
Frontal sinuses, 6

G

Gallbladder, 20
Gallbladder stones, 28
⁶⁸Ga-NOTA Glu-Urea-Lys (NGUL), 153
Gastric adenocarcinoma, 23
Gastric chamber, 102
Gastro-hepatic ligament, 92
Gastrointestinal bleeding, 248, 249
Gastrointestinal stromal tumor (GIST), 34
Genioglossus muscles, 103
Gracilis muscle, 49
Graft-versus-host disease (GVHD), 243
Greater tubercle of humerus, 236

H

Hard palate, 13, 252
Hepatic flexure of transverse colon, 269
Hepatic hilum, porta hepatis, 153
Hepatocellular carcinoma (HCC), 29, 182
Hodgkin lymphoma, 83
Hyoid bone, 62
Hypermetabolic, 7
Hypermetabolic superior mesenteric lymph nodes, 99

I

Inferior vena cava, 177
Interventricular septum, 243

L

Langerhans cell histiocytosis (LCH), 87
 Larynx, 9
 Lateral ventricle, 162
 posterior horn, 169
 Left common carotid artery, 127
 Left costovertebral junction, 134
 Left eye vitreous chamber, 4
 Left ilio-psoas muscle, 35
 Left large water bag kidney, 259
 Left medial rectus muscle, 6
 Left para pharyngeal space, 62
 Left postcentral gyrus, 2
 Left precentral gyrus, 2
 Left prostate lobe, 178
 Left quadratus lumborum muscle, 97
 Left submandibular gland, 9, 10
 Left superior frontal gyrus, 2, 55
 Left sylvian fissure, 6
 Left temporal bone, 4
 Left temporal muscle, 3
 Levator ani muscles, pubococcygeus, 96
 Liver metastases, 184
 Liver, segment VI(6), 152
 Longus capitis muscles, 11
 Lung (V/Q), 267
 Lung left upper lobe (LUL), 18
 Lymphatic system, 260
 Lymphoplasmacytic lymphoma (LPL), 3

M

Magnetic resonance artifact, 23
 Medial femoral condyle, 144
 Mesothelioma, 221
 Metabolically active cervical cancer, 41
 Metabolically active left renal cell carcinoma, 155
 Metabolically active mediastinal lymph node, 117
 Metabolically active uterine tumor with central necrosis, 119
 Meta-iodobenzylguanidine (MIBG), 198
 Midbrain, red nucleus, 6
 Mild physiologic uptake in the thymus, 107
 Myocardium, left ventricle, 172
 Myxoid liposarcoma, 49

N

Nasal septum, 7
 Nasopharyngeal squamous cell carcinoma, 7
 Nasopharynx, 10, 13
 Natural killer T-cell lymphoma (NTCL), 128
 Neuroblastoma, 198
 Neuroendocrine tumor, 186–188, 190, 191
 Normal left axillary lymph nodes, 63
 NUAT-NTCL involvement at the right anterior chest wall, 128
 Nuchal ligament, 5

O

Obturator artery, 50
 Occipital cortex, 58
 Odontoid process, 253
 Odynophagia, 64
 Oropharynx, 8, 11, 13, 88

P

Pancreas, physiologic activity, 157
 Pancreatic parenchyma, 33
 Pancreatic tail, 28
 Paraganglioma, 199
 Paraspinalis muscle, 186
 Parathyroid adenoma, 212
 Parotid glands, 252
 Patellar ligament, 144
 Pectoralis major muscles, 22
 Pericardial fat, 67
 Perilesional edema, 3
 Pineal gland, 5
 Pituitary gland, 4, 36
 Pleural mesothelioma, 80
 Positron emission tomography/computed tomography (PET/CT)
 B cell lymphoma, 63
 bilateral hilar, 69
 breast cancer, 79, 80
 ¹¹C-acetate, 154
 chest pain, 67
 chest tightness, 66
 cingulate cortex, 54
 clivus, 60
 ¹¹C-methionine, 158
 corpus callosum, 54
 ¹¹C-PIB, 162
 ductal carcinoma, 72
 ¹⁸F-Choline, 178
 ¹⁸F-FDOPA, 176
 ¹⁸F-florastamin, 175
 ¹⁸F-florbetaben, 174
 ¹⁸F-fluciclovine, 127, 146
 ¹⁸F-flumazenil, 170
 ¹⁸F-FP-CIT, 166
 Ga-arginine-glycine-aspartic acid, 172
 ⁶⁸Ga-DOTA TOC, 147–149, 151, 152
 hodgkin lymphoma, 84
 langerhans cell histiocytosis, 87
 left parietal cortex, 57
 mediastinal mass, 65
 multiple mediastinal, 78
 musculoskeletal system, 128, 130, 132–134, 138, 143, 144
 obstructive hydrocephalus, 59
 occasional dyspnea, 66
 odynophagia, 64
 paratracheal, 85
 progressive dyspnea, 67
 progressive odynophagia, 82
 progressive pain, 74
 pulmonary embolism, 70
 scalp angiosarcoma, 75
 squamous cell carcinoma, 61
 thymoma, 68
 Positron emission tomography/magnetic resonance image (PET/MRI)
 abdomen, 23, 26
 central nervous system, 2
 chest, 15, 21, 22
 cholangiocarcinoma, 29
 chronic pelvic pain, 50
 colorectal, 1
 F-Choline, 36
 F-FDG, 37, 38, 40

gastrointestinal stromal tumor, 34
 head, 2, 3
 hepatocellular carcinoma, 29
 hybrid, 1
 hypermetabolic mass, 33
 malignant transformation, 30
 musculoskeletal system, 44
 neck, 5, 10, 12, 14
 pelvis, 29
 primary tumor, 32
 sigmoid colon, 35
 Posterior arch of C1 spine, 212
 Prevesical space, 121
 Primary lung cancer, 78
 Progressive fatigue, 85
 Prostate-specific membrane antigen (PSMA), 175
 Proximal rectum, 37
 Proximal transverse colon, 115
 Pubic bone, 43
 Pulmonary embolism (PE), 70
 Pulmonary nodule, 15

Q

Quadriceps muscle, 144

R

Rectus abdominis muscles, 35
 Rectus femoris muscle, 49
 Rectus sheath, 111
 Renal, 258, 259
 Retinoblastoma, 4
 Retropharyngeal space, 12
 Right atrium, 72
 Right biceps femoris muscle, 46
 Right femoral head, 37
 Right glenoid, scapula, 17
 Right gluteus maximus muscle, 44
 Right hepatic lobe, 33
 Right interlobar artery, 70
 Right internal iliac vessels, 38, 39
 Right ischio-coccygeus muscle, 37
 Right kidney, inferior pole, 34, 110, 130
 Right lung apex, right upper lobe (RUL), 16
 Right lung, upper lobe, 73
 Right major fissure, 19
 Right masseter muscle, 7
 Right maxillary sinus, 7, 14, 238
 Right occipital horn of lateral ventricle, 174
 Right palatine tonsil, 8
 Right parotid gland, 8
 Right pectineus muscle, 141
 Right piriformis muscle, 125
 Right rectus abdominis muscle, 114
 Right sacroiliac joint, 223
 Right sartorius muscle, 44
 Right third rib posterior arc, 84

S

Sacral plexus, 50
 Salivary glands, 254
 Second portion of duodenum, 94
 Septum pellucidum, 3, 174

Single-photon emission computed tomography (SPECT)

abscess, 250
 accessory spleen, 268
 adrenal hyperplasia, 272
 benign thyroid pathology, 251, 253
 bone metastases, 224, 225, 227
 bone tumors, 222
 brain, 274, 275
 central venous line obstructio, 257
 cerebrospinal fluid, 256
 gastrointestinal bleeding, 249
 heart, 273
 hepatocellular carcinoma, 182
 liver metastases, 183, 185
 lung (V/Q), 265, 267
 lymphatic system, 261, 264
 mesothelioma, 221
 neuroblastoma, 198
 neuroendocrine tumor, 187, 189, 191, 193, 195
 non tumorous conditions, 228, 232, 234, 239, 240, 242
 paraganglioma, 200
 parathyroid adenoma, 217, 218
 renal, 259
 salivary glands, 254
 thyroid cancer, 205, 211
 Skull base metastasis involving the left clivus, 133
 Small bowel loops, 95, 111, 152
 Small bowel mesentery, 259
 Sphenoid sinus, 10, 13
 Spinal cord, 5, 10
 Spleen, 33, 124
 Strap muscles, 176
 Submandibular glands, 62, 205
 Superior mesenteric artery, 99
 Superior vena cava, 143
 Suprasellar germinoma, 59
 Suprasellar region, 59

T

Takayasu arteritis, 86
 Thalamus, 5, 132
 Thoracic vertebral body, 24, 150
 Thymoma type B1, 67
 Thyroid cancer, 201
 Tibial shaft, 48
 Tortuous thoracoabdominal aorta, 109
 Trachea, 12, 13
 Transverse colon, 20, 33, 152, 153, 245
 Trapezius muscle, 212
 Tuberculosis, 21

U

Uncinate process of the pancreas, 271
 Undifferentiated pleomorphic sarcoma (UPS), 139
 Urinary bladder, 43, 93

W

Waldenström macroglobulinemia (WM), 3

X

Xiphoid process, 132
