Abstract

Hereditary hemochromatosis (HH) is a common genetic metabolic disorder characterized by excessive iron absorption and elevated serum iron levels, which accumulate in various organs, such as the heart, pancreas, gonads, and damage these organs. There are only a few articles and clinical studies describing the characteristics of cardiac involvement in HH along with the significance of early diagnosis and management in preventing complications. In this review article, we have reviewed multiple pieces of literature and gathered available information regarding the subject. We compiled the data to investigate the importance of early detection of symptoms, regular monitoring, and

Nov 2019 | CA-A CANCER JOURNAL FOR CLINICIANS 69 (6), pp.438-451

This article is the American Cancer Society's biennial update on female breast cancer statistics in the United States, including data on incidence, mortality, survival, and screening. Over the most recent 5-year period (2012-2016), the breast cancer incidence rate increased slightly by 0.3% per year, largely because of rising rates of local stage and ho ... [Show more](#)

Anemia and Pregnancy

Anemia is defined as a hemoglobin (Hb) value less than the lower limit of normal that is not explained by the state of hydration. This definition has physiologic validity, in that it is the amount of Hb per unit volume of blood that determines the oxygen-carrying capacity of blood. The normal Hb level for the adult female is 14.0 ± 2.0 g/dL.¹ However, in pregnancy, because of the greater increase in plasma volume compared with red cell mass (i.e., hemodilution of pregnancy), anemia is defined by the Centers for Disease Control and Prevention (CDC) as an Hb concentration lower than 11 g/dL in the first and third trimesters, or lower than 10.5 g/dL in the second trimester.² Of note, definitions of anemia vary across publications. Between 1995 and 2011, the global incidence of anemia (Hb level of less than 11 g/dL throughout pregnancy) in pregnant women fell from 43% to 38%, and in one-half of cases anemia was caused by iron deficiency.³ In this same study, the incidence in pregnant women from high-income regions was 22% and approximately 17% in the US.

³ Defining anemia as an Hb level of less than 12 g/dL, the incidence of anemia was 6.9% in US nonpregnant women younger than 50 years of age.⁴ The incidence of anemia (Hb level < 12 g/dL)

Enabling X-ray free electron laser crystallography for challenging biological systems from a limited number of crystals.

Bottom Line: We implemented a data processing system based on classical post-refinement techniques, adapted to specific properties of XFEL diffraction data. Moreover, the number of observations for a reflection necessary to assemble an accurate data set could be reduced to a few observations. These developments will help expand the applicability of XFEL crystallography to challenging biological systems, including cases where sample is limited.

fig7: Quality of synchrotron vs. post-refined XFEL diffraction data sets for **myoglobin**. Difference Fourier (mFo-DFo) omit maps at 1.35 Å around the heme group (which was omitted from molecular replacement and model refinement), generated from (A) the synchrotron diffraction data and corresponding model with PDB ID 1JW8 (for comparison, all reflections past 1.35 Å resolution were excluded) and (B) the post-refined **myoglobin** XFEL diffraction data set using all 757 diffraction images (Table 1). The maps are contoured at 2.5 σ . DOI: <http://dx.doi.org/10.7554/eLife.05421.013>
